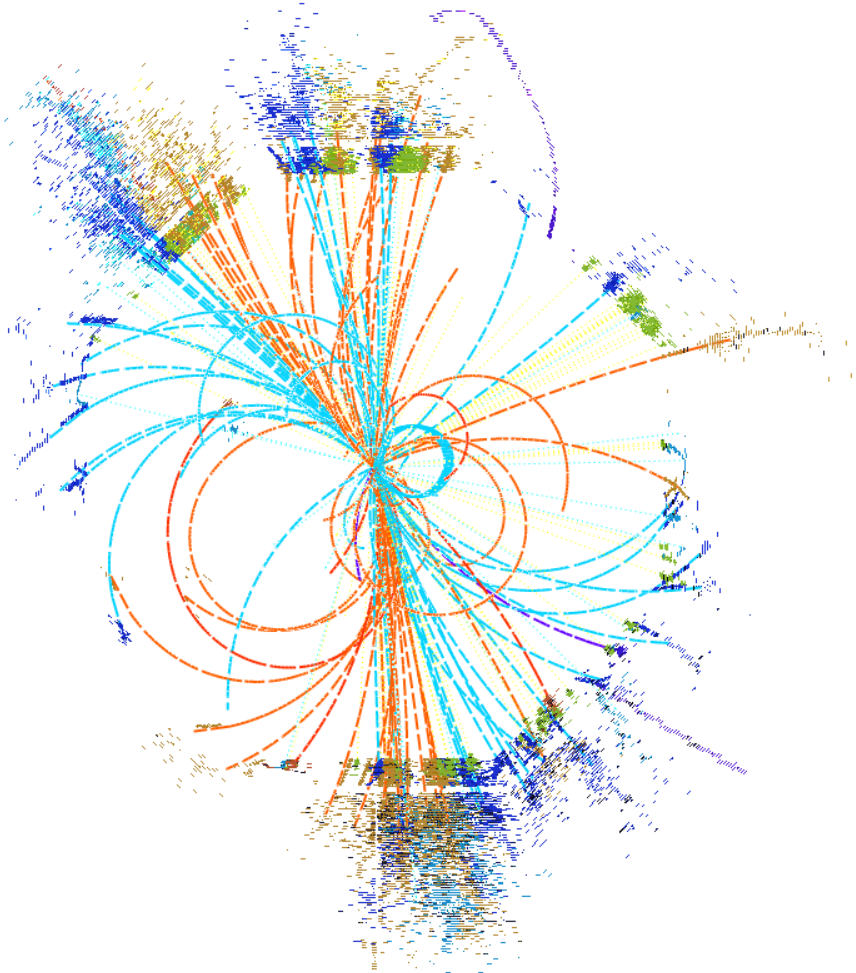
Physics and detectors at CLIC

Philipp Roloff (CERN)
on behalf of the CLIC physics and detector study



Physics Seminar, KEK, 08/06/2012

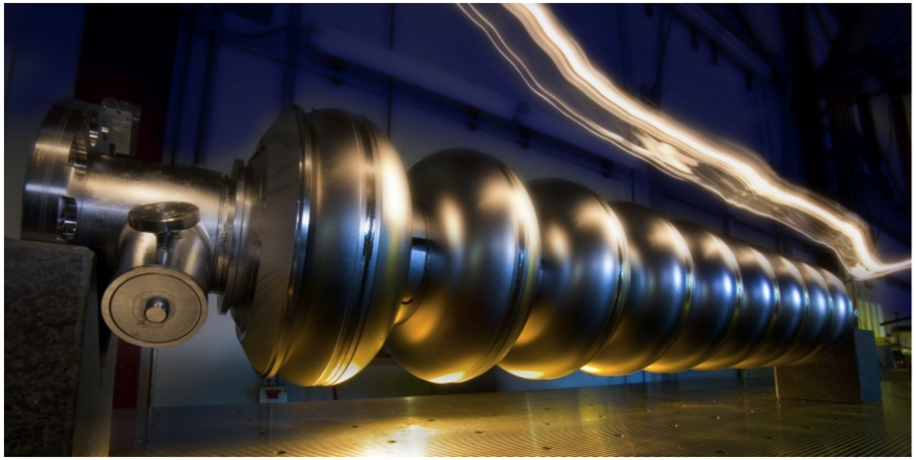
Outline

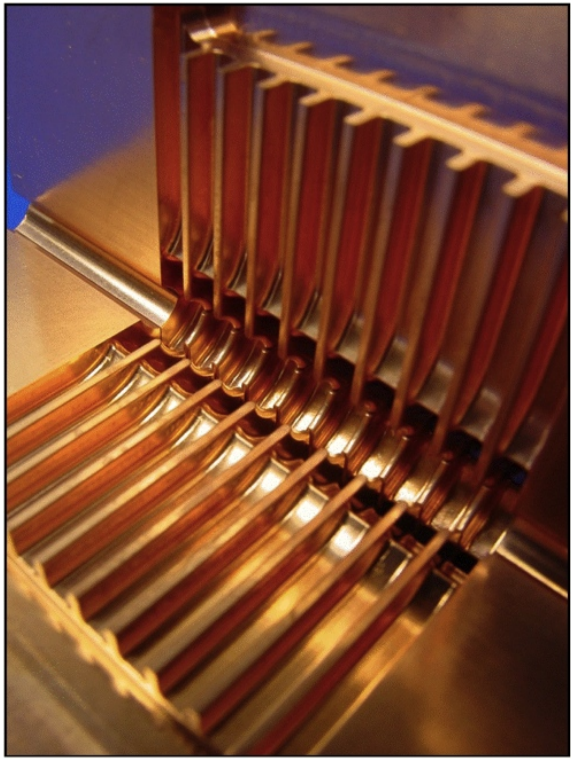
- The CLIC accelerator
- Physics at CLIC
- Detector requirements
- The CLIC_ILD and CLIC_SiD detectors
- Background suppression & event reconstruction
- Physics benchmark studies
- CLIC energy staging
- Beyond the CDR
- Summary and conclusions

The CLIC accelerator

CLIC and ILC

e^+e^- collisions at high energies → linear accelerators





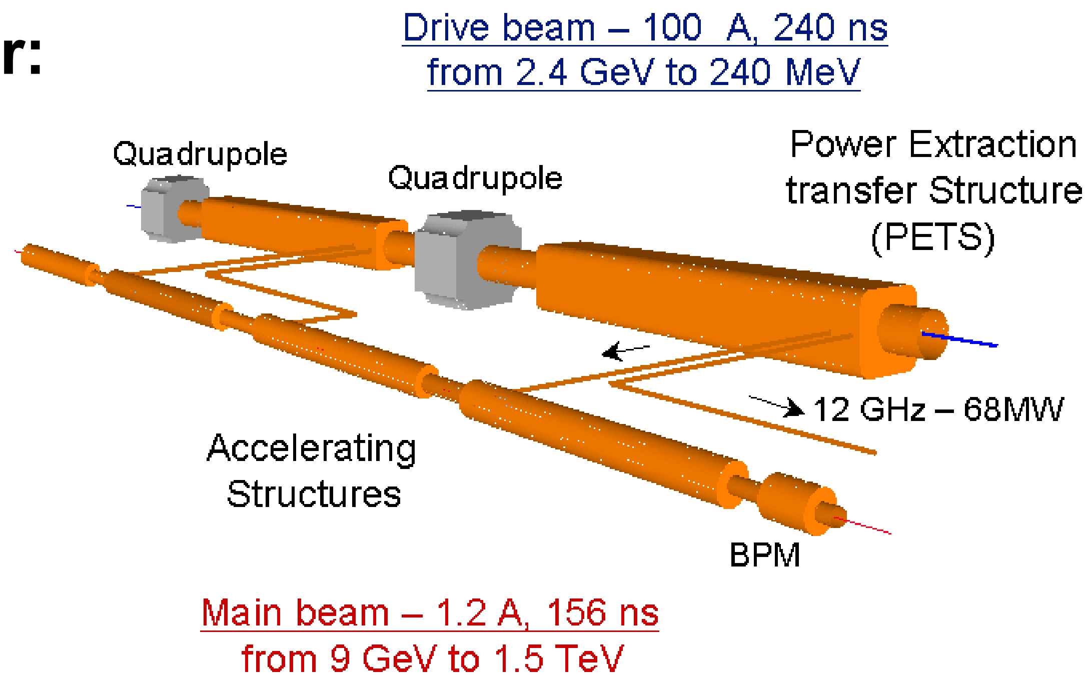
International Linear Collider (ILC):
• Based on superconducting RF cavities (like XFEL)
• Gradient: 32 MV/m
• Energy: 500 GeV, upgradable to 1 TeV
• Detector studies focussed mostly on up to 500 GeV, work for 1 TeV ongoing

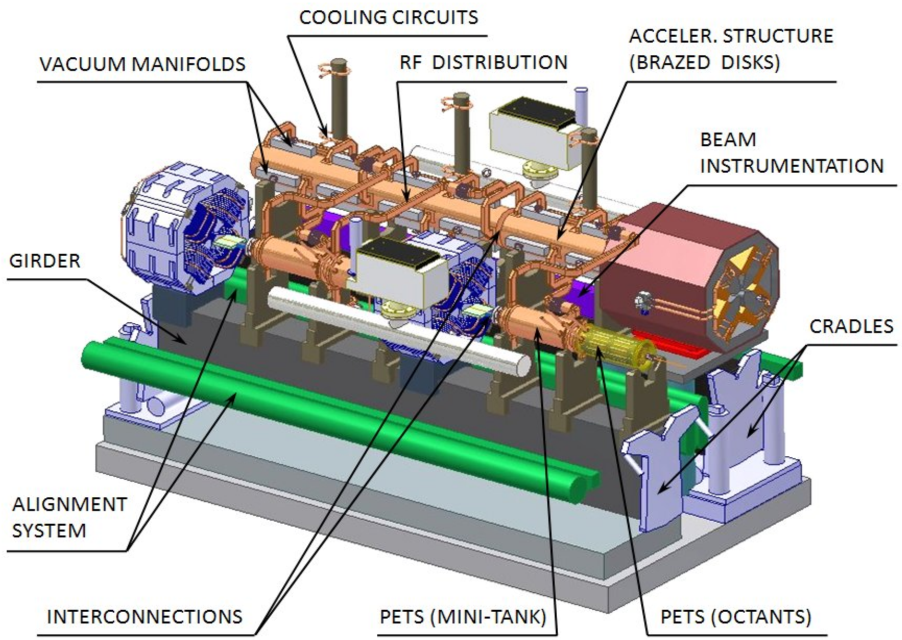
Compact Linear Collider (CLIC):
• Based on 2-beam acceleration scheme
• Operated at room temperature
• Gradient: 100 MV/m
• Energy: 3 TeV, staged construction in steps starting from few hundred GeV possible
• Detector study focusses on 3 TeV, investigation of lower energies in progress

Luminosities: few 10^{34} $cm^{-2}s^{-1}$

2-beam acceleration scheme

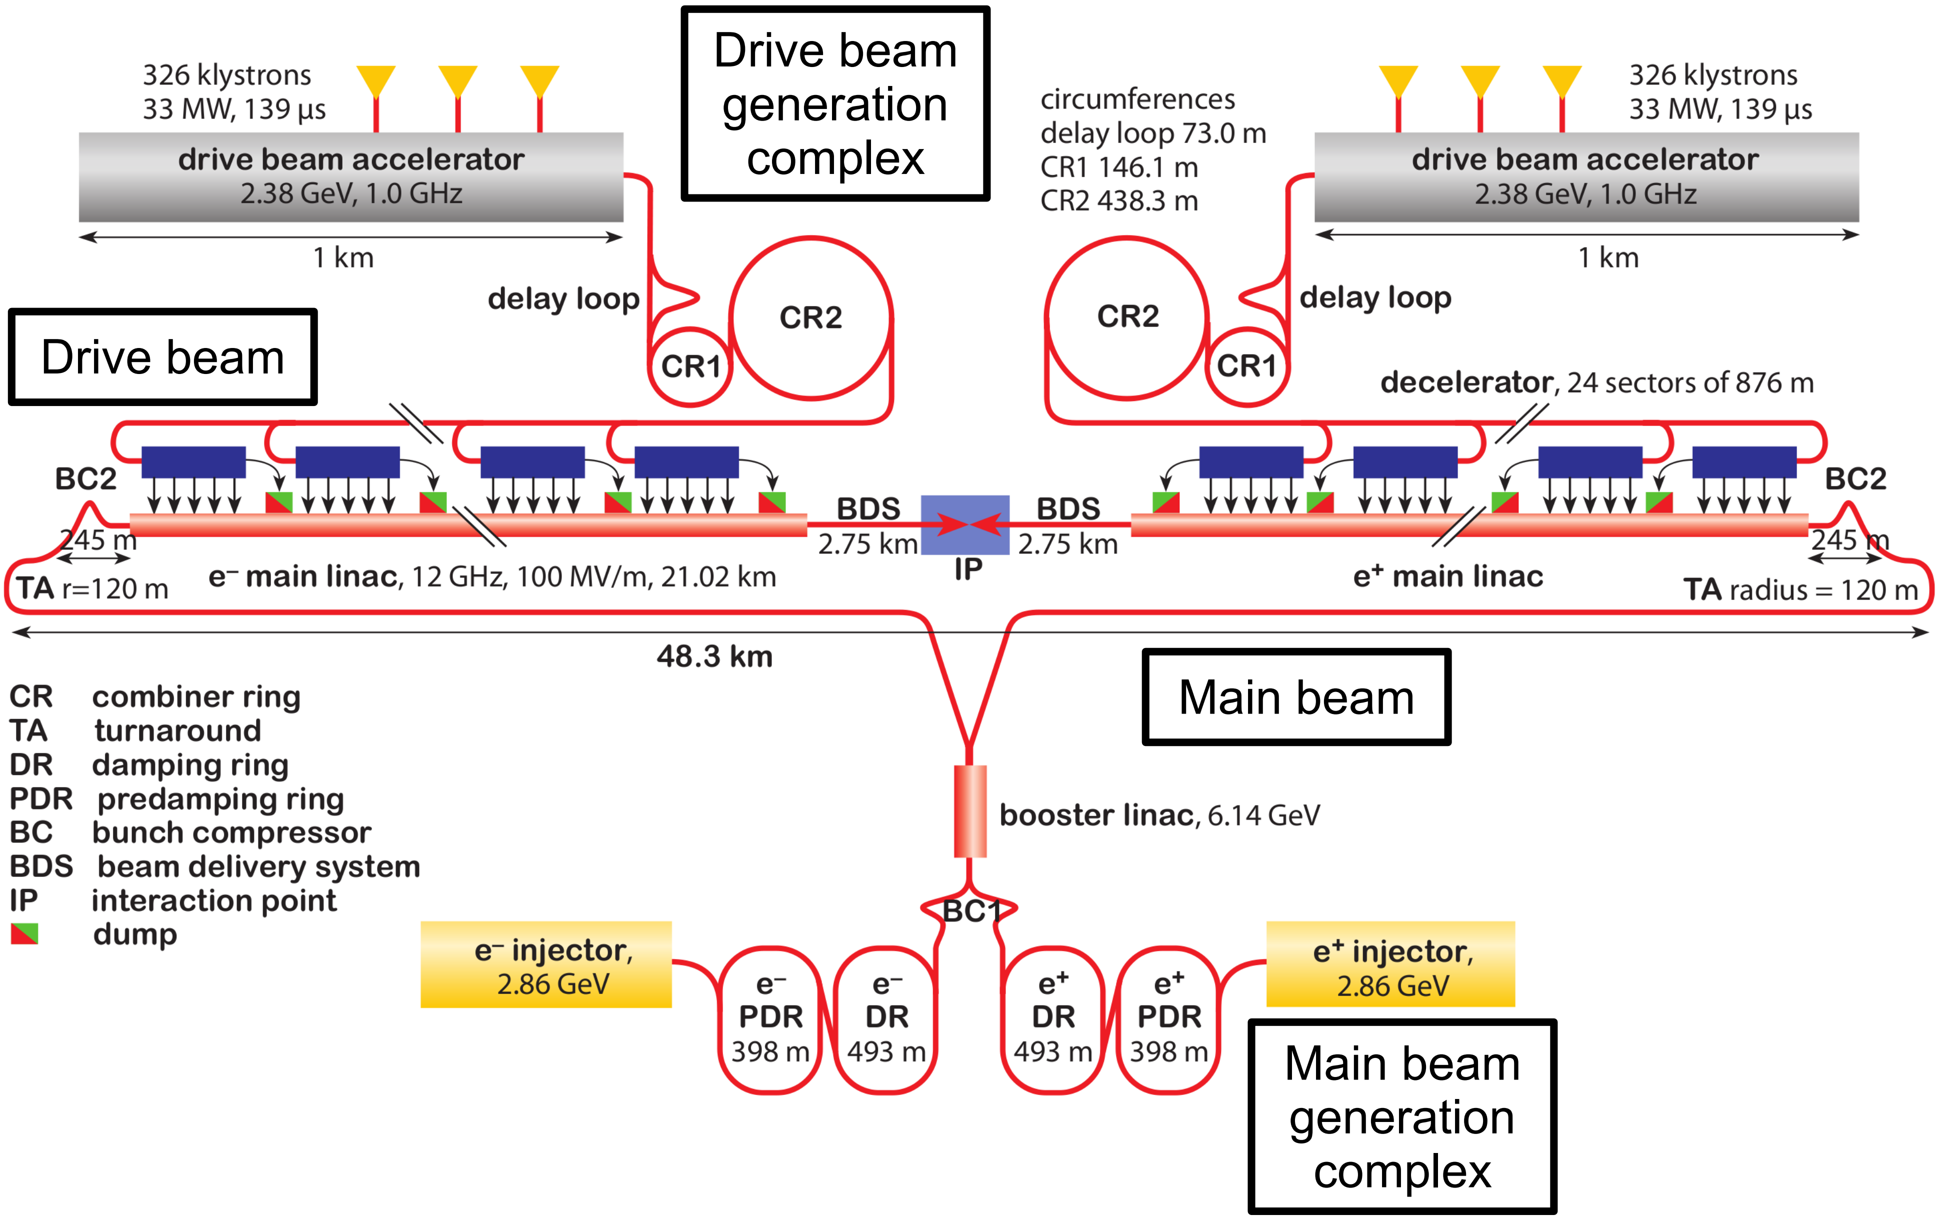
Drive beam supplies RF power:
- 12 GHz bunch structure
- Low energy:
2.4 GeV – 240 MeV
- High current: 100 A





Main beam for physics:
- High energy: 9 GeV – 1.5 TeV
- Current: 1.2 A

CLIC accelerator complex

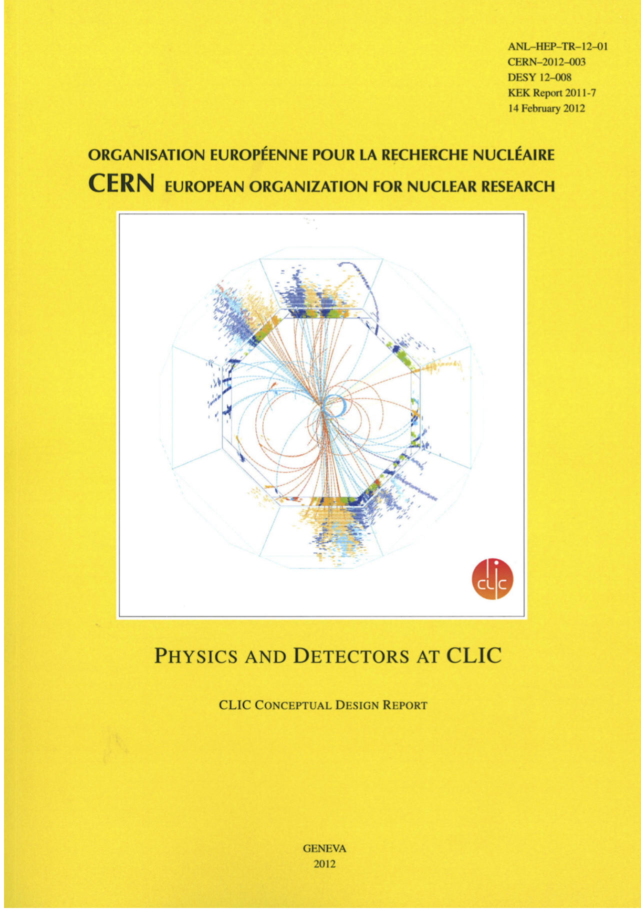


CLIC status

- Conceptual Design Report (CDR) stage just finished
- Moving towards a technical design phase

Three volumes of the CLIC CDR:

1. Accelerator:
   - No show-stoppers identified
   - Accelerating gradient in reach
   - Officially presented to CERN SPC, final text editing ongoing
2. Physics and detectors:
   - Published: http://arxiv.org/abs/1202.5940
3. Strategic CDR volume:
   - Energy staging, cost, …
   - In progress, ready summer 2012



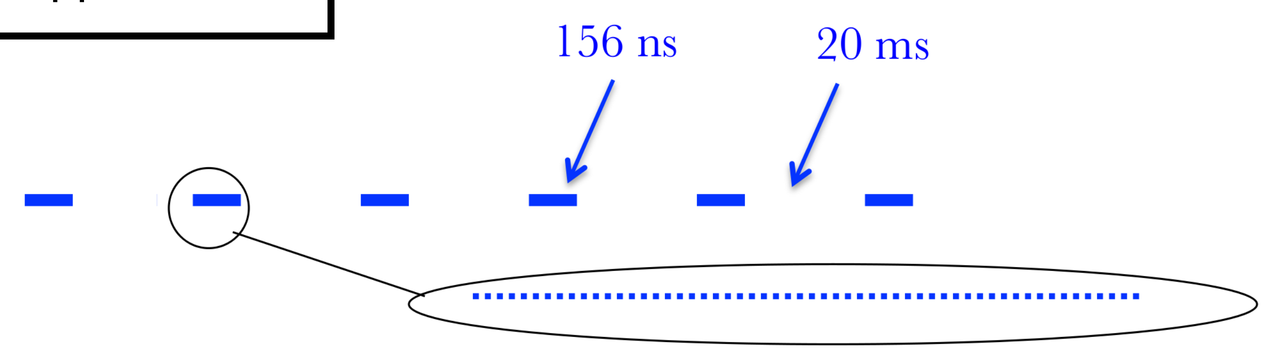
Signatories list of the CDR:
http://indico.cern.ch/conferenceDisplay.py?confId=136364

Selected CLIC parameters

	CLIC at 3 TeV
L ($cm^{-2}s^{-1}$)	$5.9 \cdot 10^{34}$
Bunch separation	0.5 ns
#Bunches / train	312
Train duration	156 ns
Train rep. rate	50 Hz
Crossing angle	20 mrad
Particles / bunch	$3.72 \cdot 10^{9}$
σ_x/σ_y (nm)	≈ 45 / 1
σ_z (μm)	44

Drive timing requirements for CLIC detector

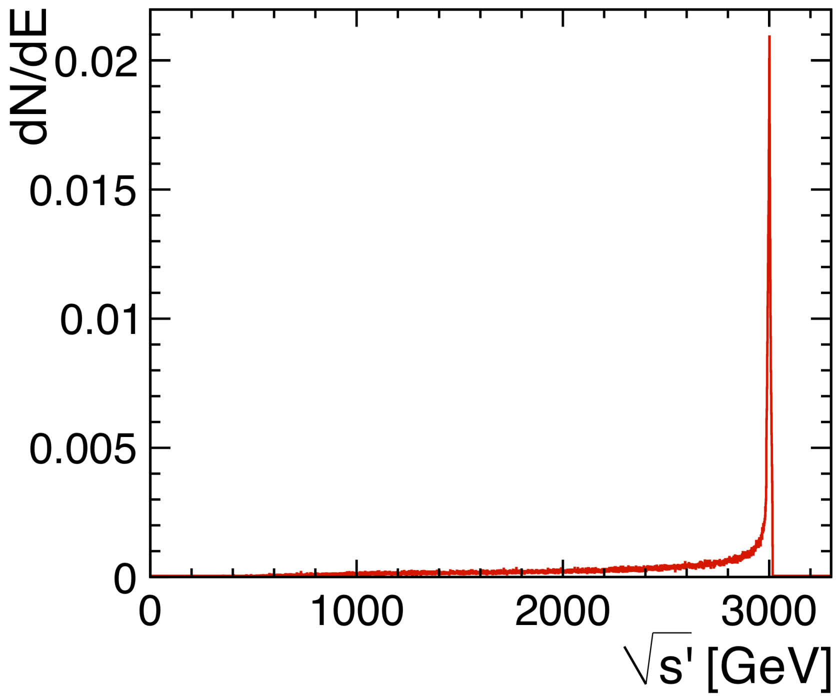
Very small beam profile at the interaction point



CLIC: trains at 50 Hz, 1 train = 312 bunches, 0.5 ns apart

Luminosity spectrum

Significant energy loss at the interaction point due to Beamstrahlung

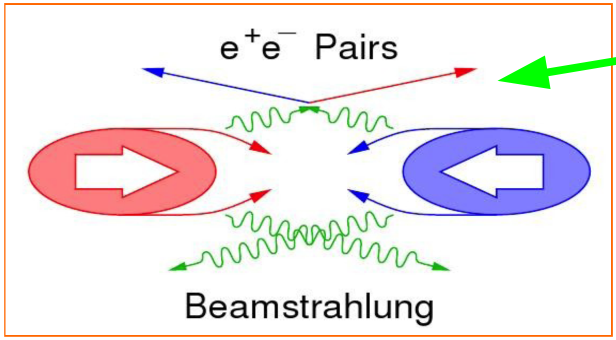


Full luminosity: $L = 5.9 \cdot 10^{34}\ \mathrm{cm^{-2}s^{-1}}$
In the most energetic 1% (“peak luminosity”):
$L_{0.01} = 2.0 \cdot 10^{34}\ \mathrm{cm^{-2}s^{-1}}$

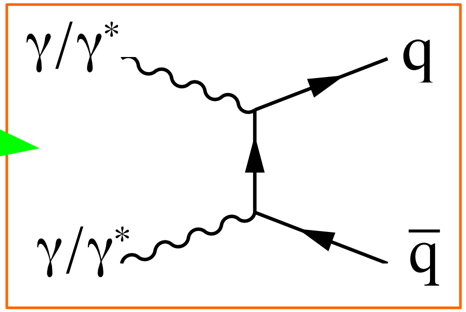
Most physics processes are studies
well above the production threshold
→ Profit from (almost) full luminosity

$$\sqrt{s'} = \sqrt{4 \cdot E_1 \cdot E_2}$$

Beam related backgrounds



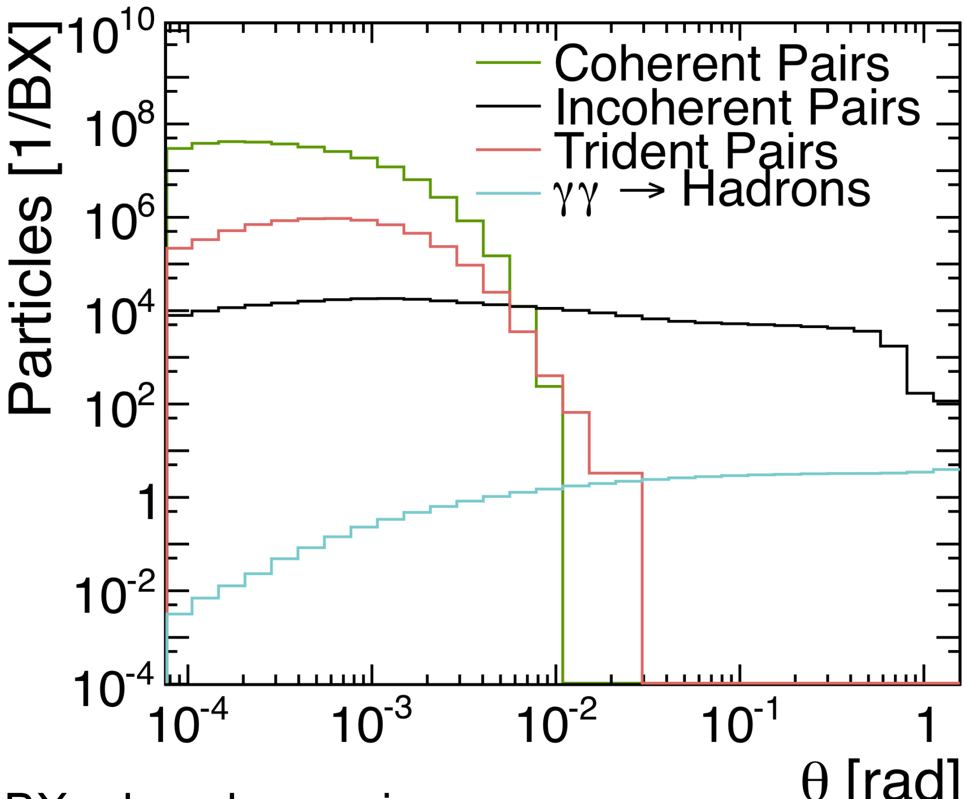
- e^+e^- pairs
- $\gamma\gamma \rightarrow$ hadrons
- Beam halo muons



Coherent e^+e^- pairs:
$7 \cdot 10^8$ per BX, very forward
Incoherent e^+e^- pairs:
$3 \cdot 10^5$ per BX, rather forward
→ Detector design issue
(high occupancies)

$\gamma\gamma \rightarrow$ hadrons
- "Only" 3.2 per BX
- Main background

in calorimeters and trackers
→ Impact on physics



BX = bunch crossing

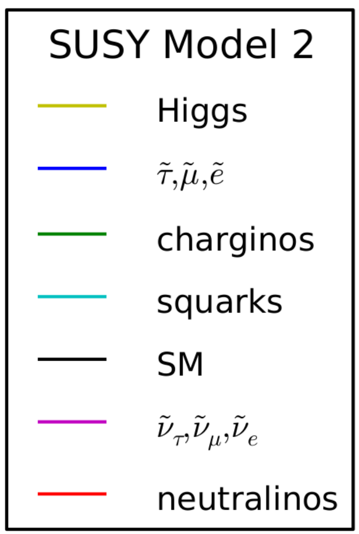
Physics at CLIC

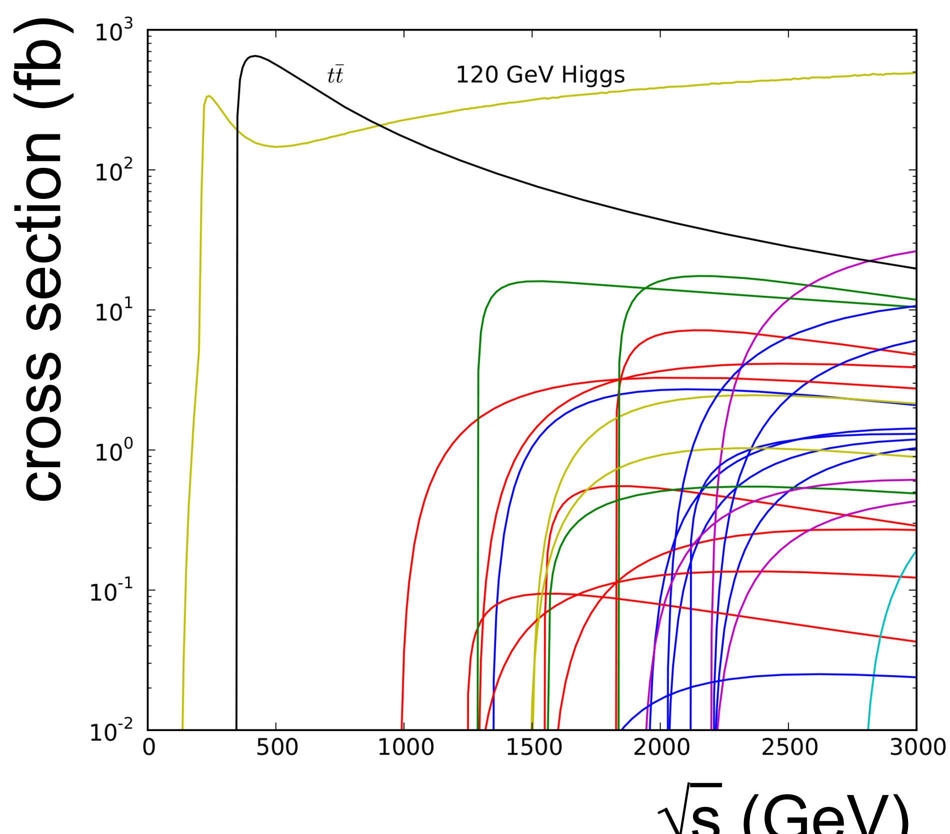
CLIC physics potential

Advantage of e+e- collisions:
- Defined initial state
- Precision measurements possible due to clean conditions
- Well suited for weakly interacting states (e.g. sleptons, gauginos)
- Polarised (electron) beam

→ **Complementary / enhanced discovery reach compared to the LHC**

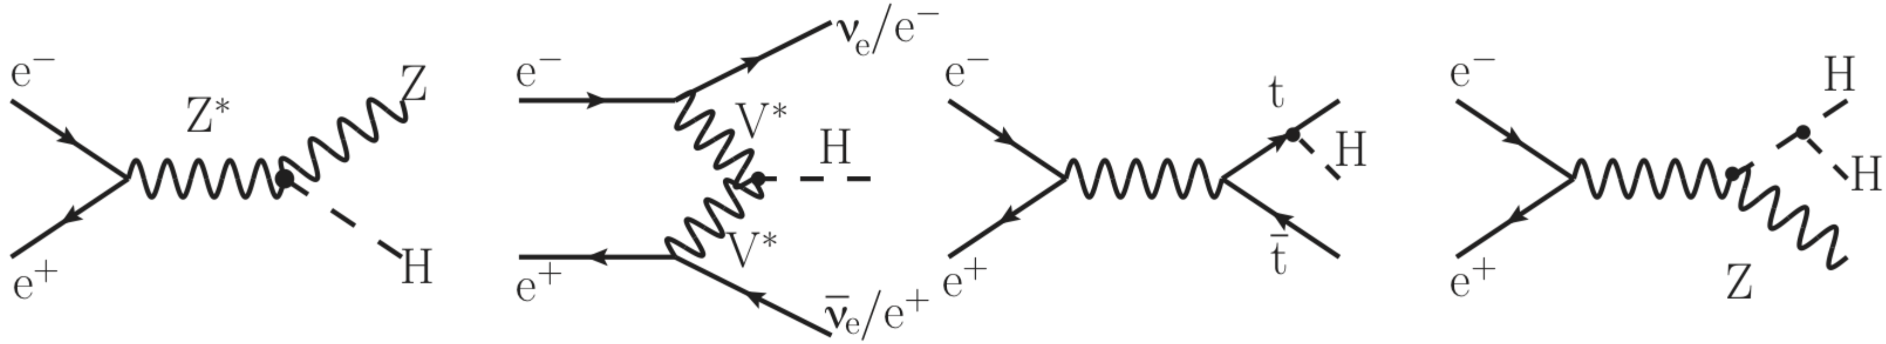
Examples highlighted in the CDR:
- Higgs physics (SM and non-SM)
- Top physics
- SUSY
- Higgs strong interactions
- Z'
- Contact interactions
- Extra dimensions
- …





All studies shown in the following are based on full detector simulation (Geant4)

SM Higgs production

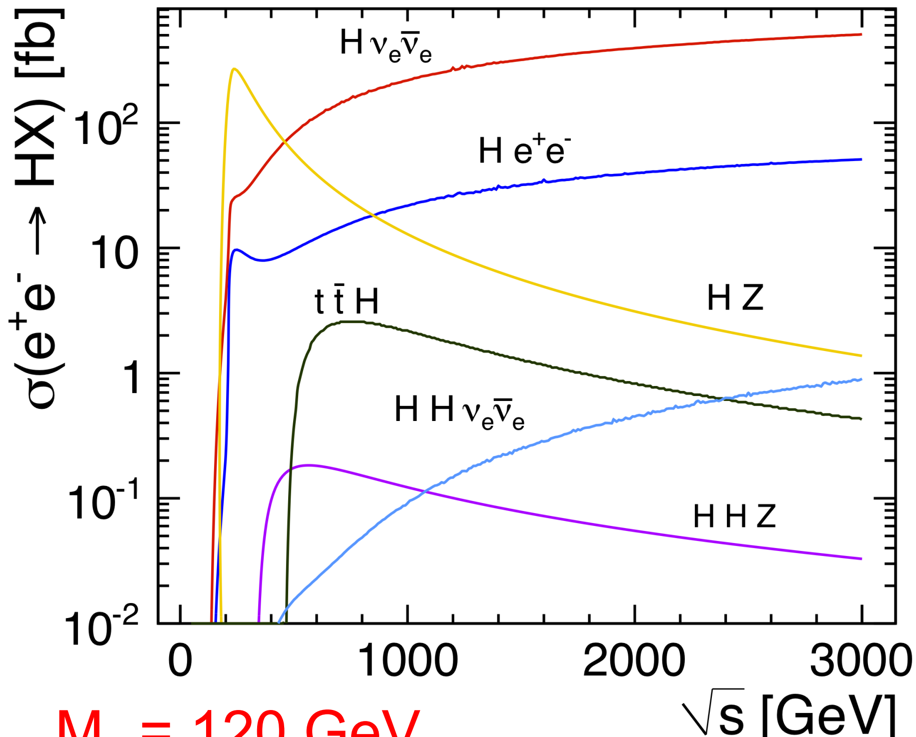


s-channel: ~ 1/s

t-channel: ~ log(s)

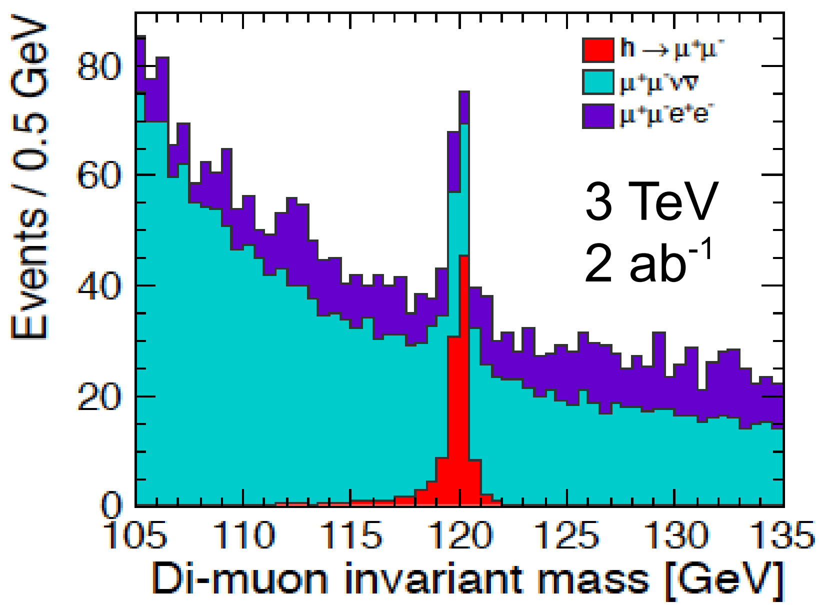
At $\sqrt{s}$ = 3 TeV:

- WW fusion ($e^+e^- \rightarrow H\nu_e\bar{\nu}_e$) dominant
- Highest peak luminosity available

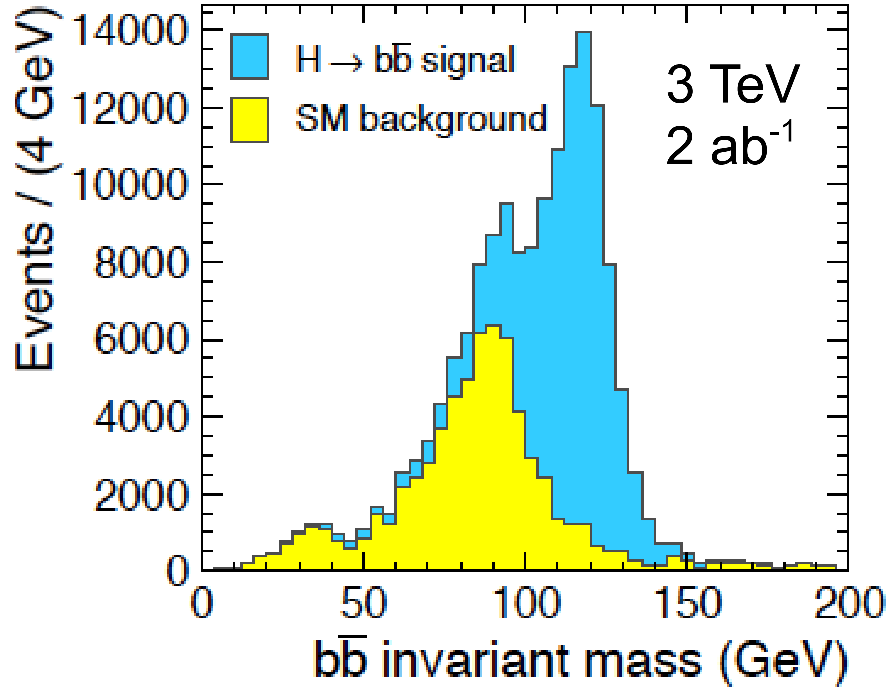


M_h = 120 GeV

Example Higgs observables



$\sigma(h \rightarrow \mu^+\mu^-) \rightarrow \pm 15\%$ (stat.)



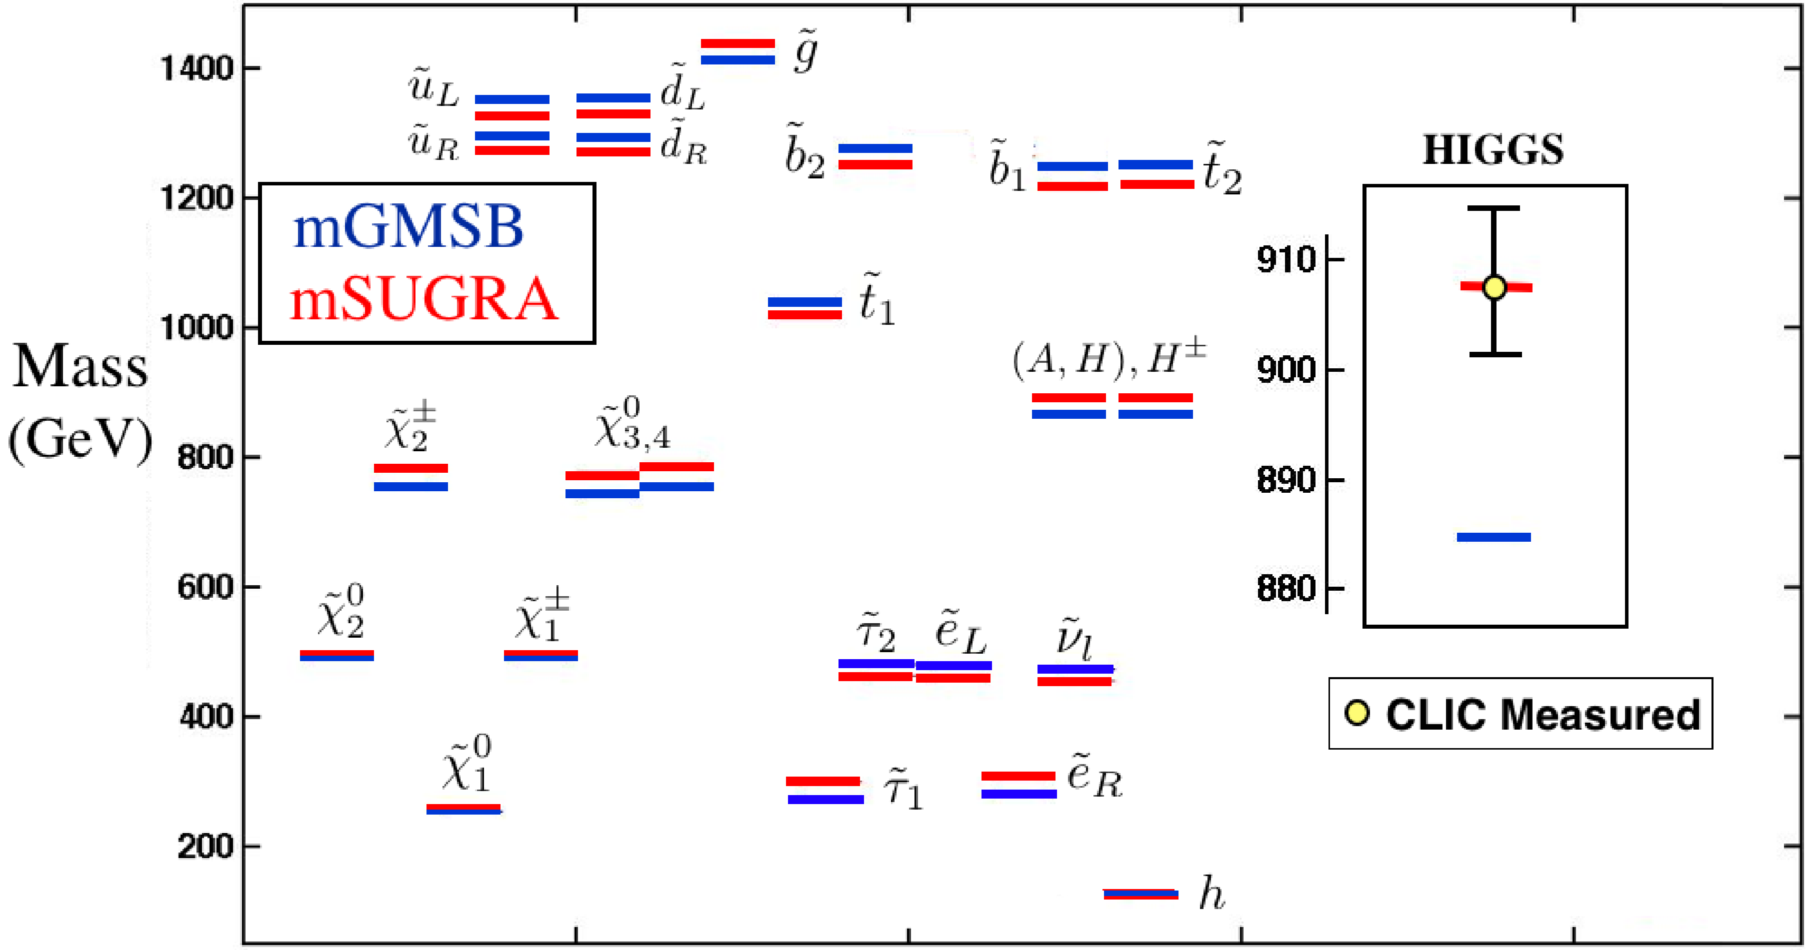
$\sigma(h \rightarrow b\bar{b}) \rightarrow \pm 0.22\%$ (stat.)

	Coupling determination(%)	Sensitivity to SM deviation (%)
Hbb	2	4
Hcc	3	6
$H\mu\mu$	15	15

Resolving new physics models

Precision measurements at CLIC allow to discriminate between new physics models, e.g. following first observations at the LHC

Example: SUSY breaking models with nearly degenerate mass spectra



Overview of physics reach

Indicative discovery reach:

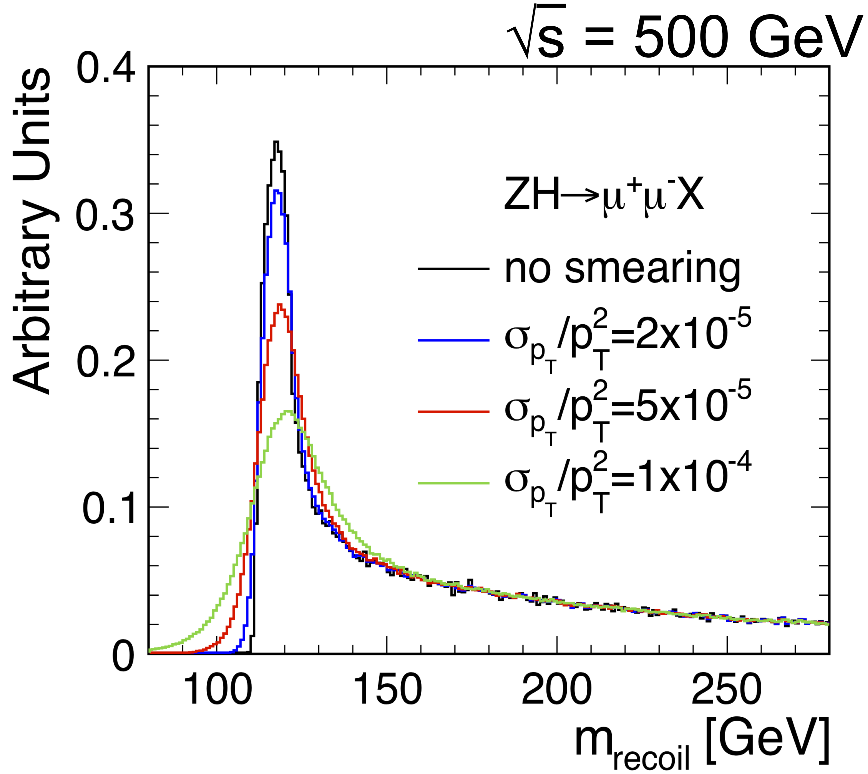
New particle	collider: $\mathscr{L}$:	LHC14 100 fb^{-1}	SLHC 1 ab^{-1}	LC800 500 fb^{-1}	CLIC3 1 ab^{-1}
squarks [TeV]		2.5	3	0.4	1.5
sleptons [TeV]		0.3	-	0.4	1.5
Z' (SM couplings) [TeV]		5	7	8	20
2 extra dims M_D [TeV]		9	12	5-8.5	20-30
TGC (95%) (λ_γ coupling)		0.001	0.0006	0.0004	0.0001
μ contact scale [TeV]		15	-	20	60
Higgs compos. scale [TeV]		5-7	9-12	45	60

Detector requirements

Physics aims → detector needs

- **Momentum resolution**
(e.g. Higgs recoil mass, h → $\mu^+\mu^-$, leptons from BSM processes)

$$\frac{\sigma(p_T)}{p_T^2} \sim 2\times10^{-5}\,GeV^{-1}$$



- **Jet energy resolution**
(e.g. W/Z/h separation)

$$\frac{\sigma(E)}{E} \sim 3.5-5\%\ for\ E=1000-50\,GeV$$

- **Impact parameter resolution**
(b/c tagging, e.g. Higgs couplings)

$$\sigma(d_0)=\sqrt{a^2+b^2\cdot GeV^2/(p^2\sin^3\theta)},\ a\approx5\,\mu m,\ b\approx15\,\mu m$$

- **Lepton identification, very forward electron tagging**

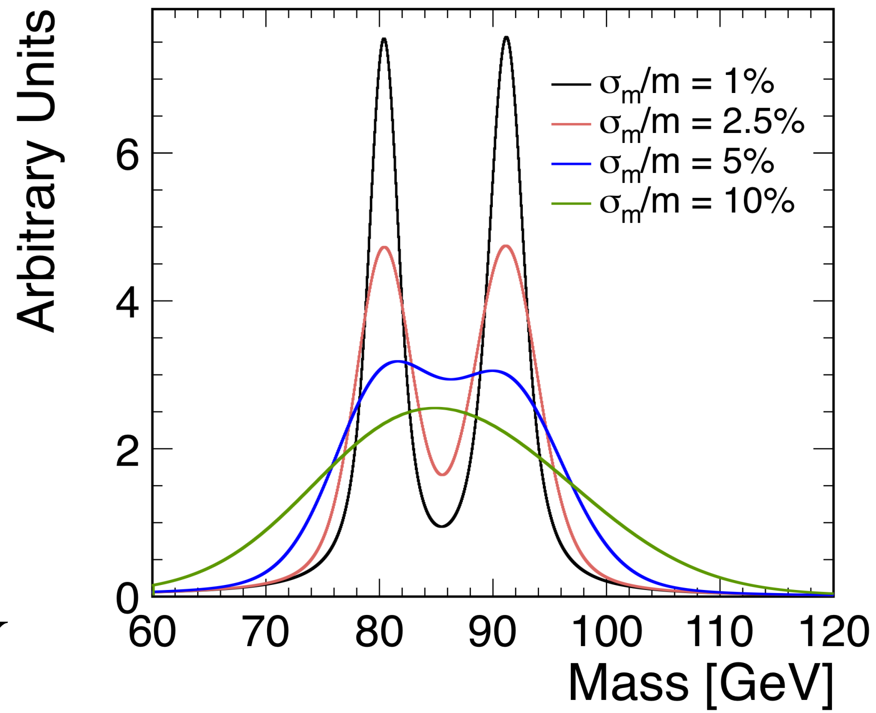
Physics aims → detector needs

- **Momentum resolution**
(e.g. Higgs recoil mass, h → μ⁺μ⁻, leptons from BSM processes)

$$\frac{\sigma(p_T)}{p_T^2} \sim 2\times 10^{-5}\, GeV^{-1}$$

- **Jet energy resolution**
(e.g. W/Z/h separation)

$$\frac{\sigma(E)}{E} \sim 3.5-5\%\ for\ E = 1000-50\, GeV$$



- **Impact parameter resolution**
(b/c tagging, e.g. Higgs couplings)

$$\sigma(d_0) = \sqrt{a^2 + b^2 \cdot GeV^2/(p^2 \sin^3\theta)},\ a \approx 5\,\mu m,\ b \approx 15\,\mu m$$

- **Lepton identification, very forward electron tagging**

Physics aims → detector needs

- **Momentum resolution**

(e.g. Higgs recoil mass, h → $\mu^+\mu^-$, leptons from BSM processes)

$$\frac{\sigma(p_T)}{p_T^2} \sim 2\times10^{-5}\, GeV^{-1}$$

- **Jet energy resolution**

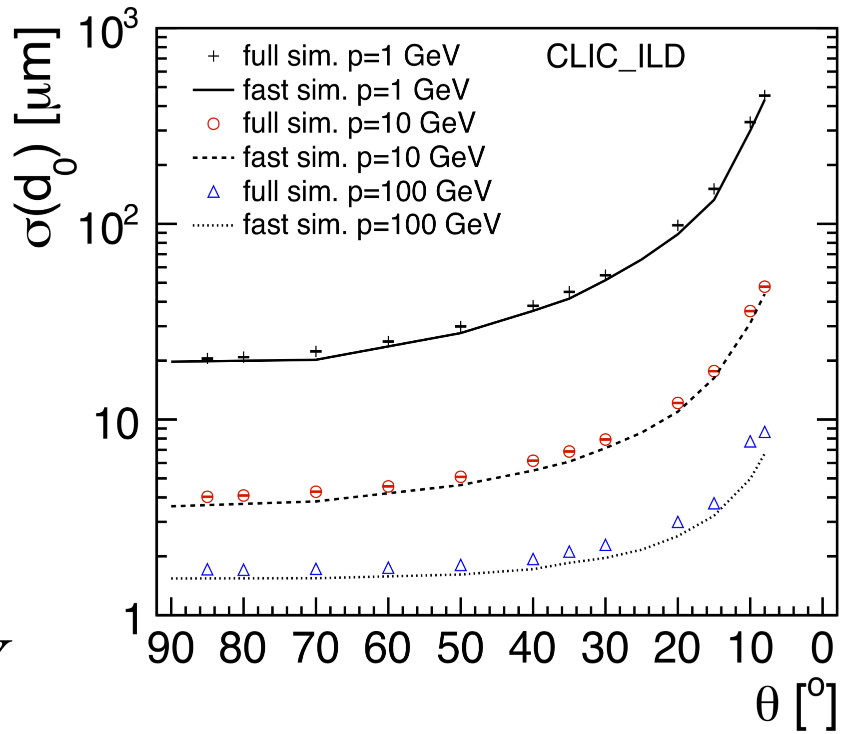
(e.g. W/Z/h separation)

$$\frac{\sigma(E)}{E} \sim 3.5-5\%\ for\ E=1000-50\, GeV$$

- **Impact parameter resolution**

(b/c tagging, e.g. Higgs couplings)

$$\sigma(d_0)=\sqrt{a^2+b^2\cdot GeV^2/(p^2\sin^3\theta)},\ a\approx5\,\mu m,\ b\approx15\,\mu m$$



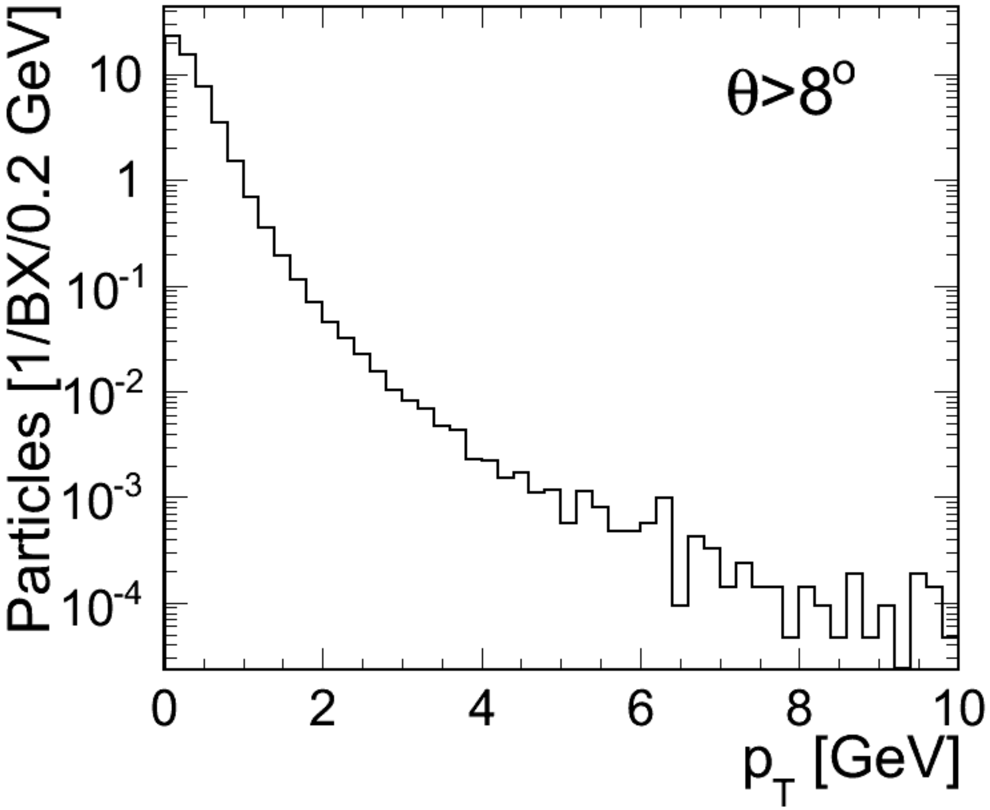
- **Lepton identification, very forward electron tagging**

General readout considerations

3.2 γγ → hadr. interactions per bunch crossing:

• 19 TeV in the calorimeters per 156 ns bunch train

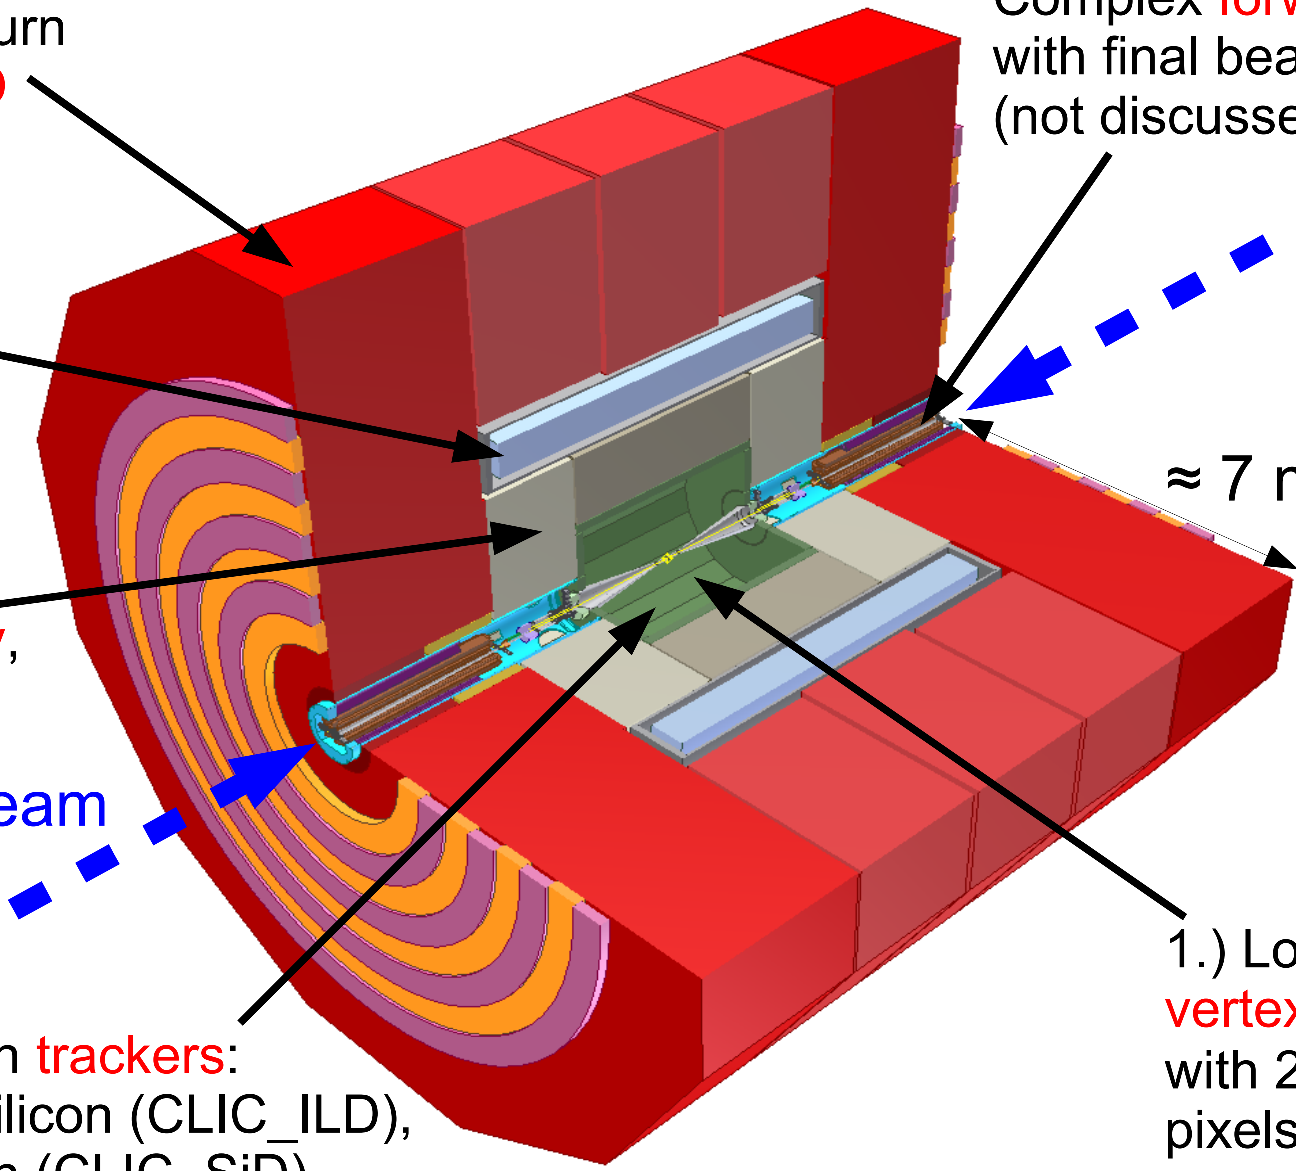
• 5000 tracks with a total momentum of 7.3 TeV



Triggerless readout of full bunch train:
• Time-stamping in tracking detectors and calorimeters
• Multi-hit storage / readout
• Filtering algorithms at reconstruction level (→ later)

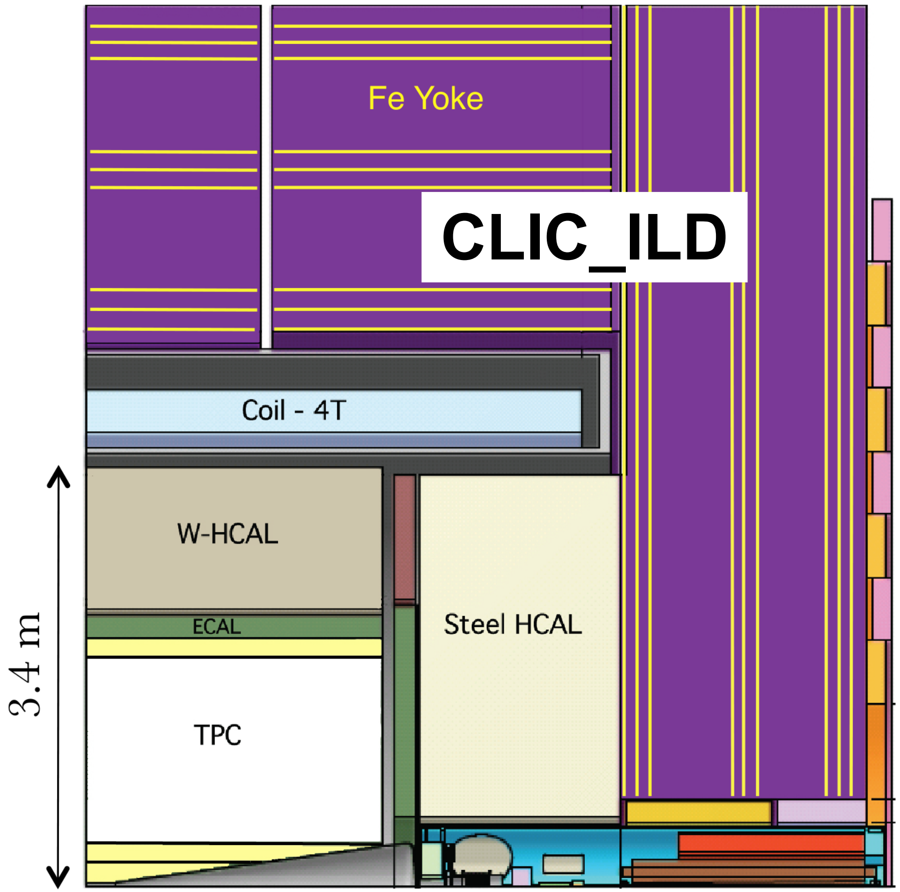
The CLIC_ILD and CLIC_SiD detectors

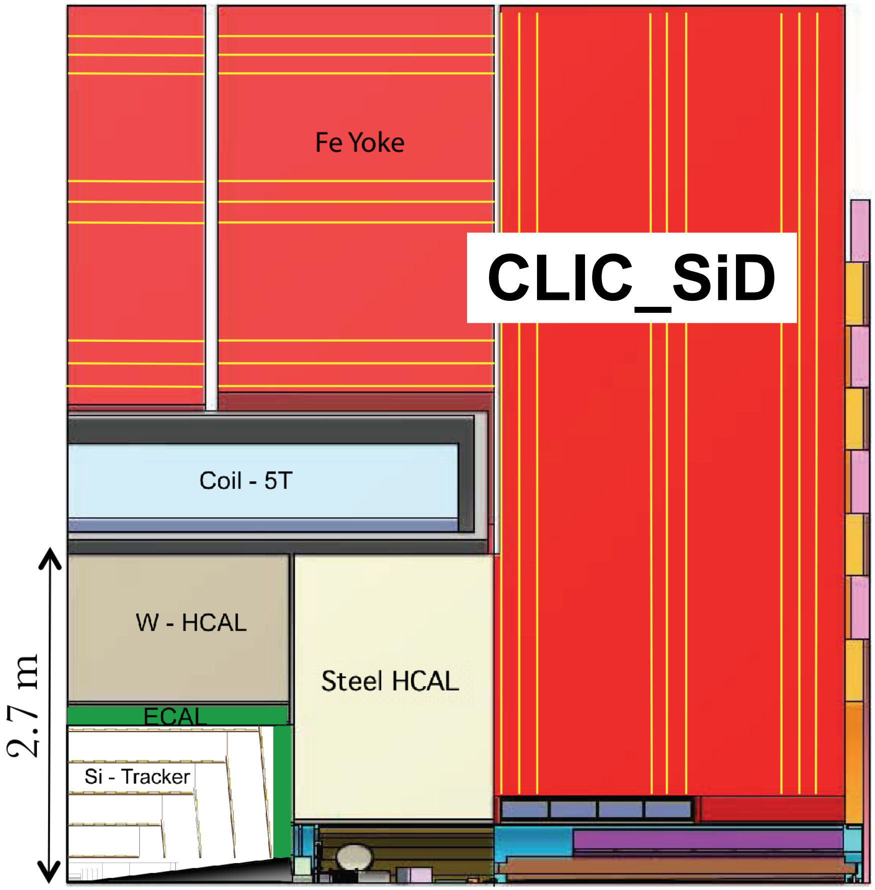
Detector overview



CLIC detector concepts

Based on validated ILC designs, adapted and optimised to the CLIC conditions:
- Denser HCAL in the barrel (Tungsten, 7.5 λ)
- Redesign of the vertex and forward detectors (backgrounds)
- Precise timing capabilities of most subdetectors



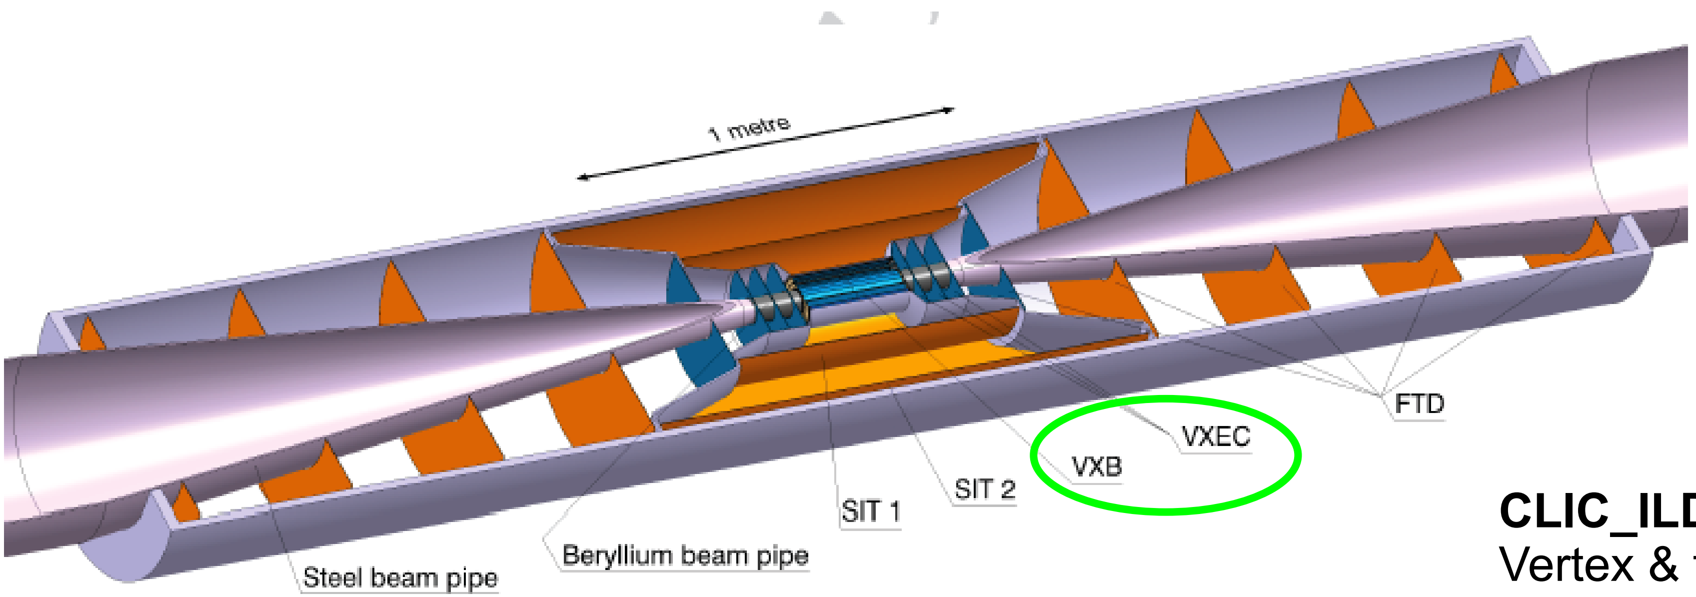


Vertex detectors

Vertex detector requirements

Requirements:

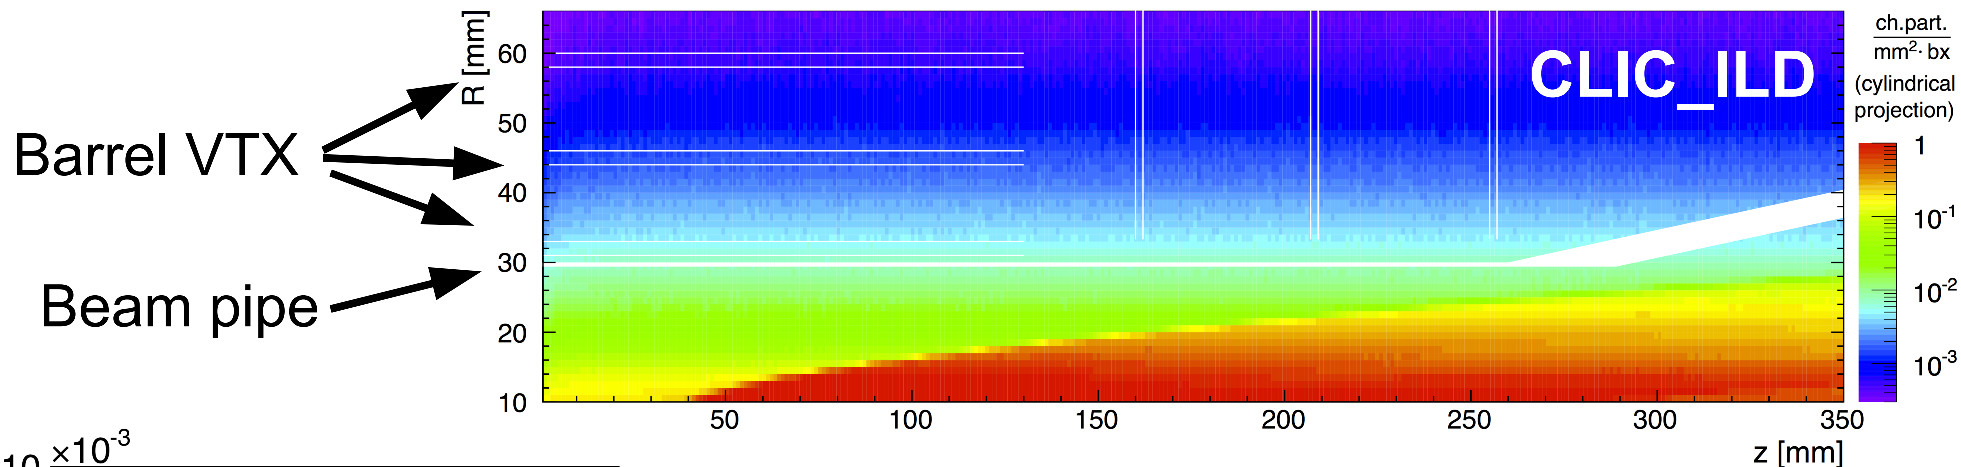
- 20 x 20 μm^2 pixel size
- Material: 0.2% X_0 per layer:
  - Very thin materials / sensors
  - Low-power design, power pulsing, low-mass cooling
- Time stamping precision: ≈10 ns (to reject backgrounds)
- Radiation level: ≈10^{10} n_{eq} /cm^2 /yr (10^{-4} of LHC)

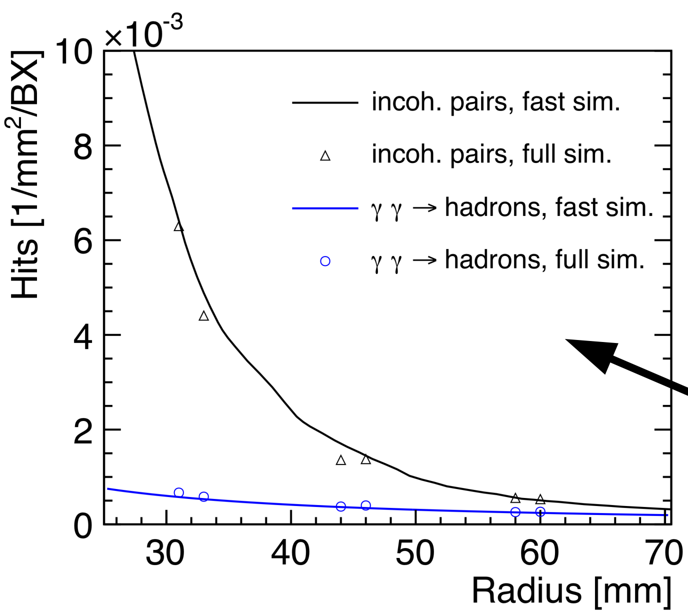


CLIC_ILD:
Vertex & forward tracking

Vertex detector backgrounds

Incoherent pair background determines:
Locations of vertex detector & forward tracking disks, design of beam pipe





- Pair background mostly at low radii

- Inner radius of barrel vertex detector: 31 mm (CLIC_ILD), 27 mm (CLIC_SiD)

- Barrel: up to 1.9% train occupancy / pixel
- Forward: up to 2.9% train occupancy / pixel

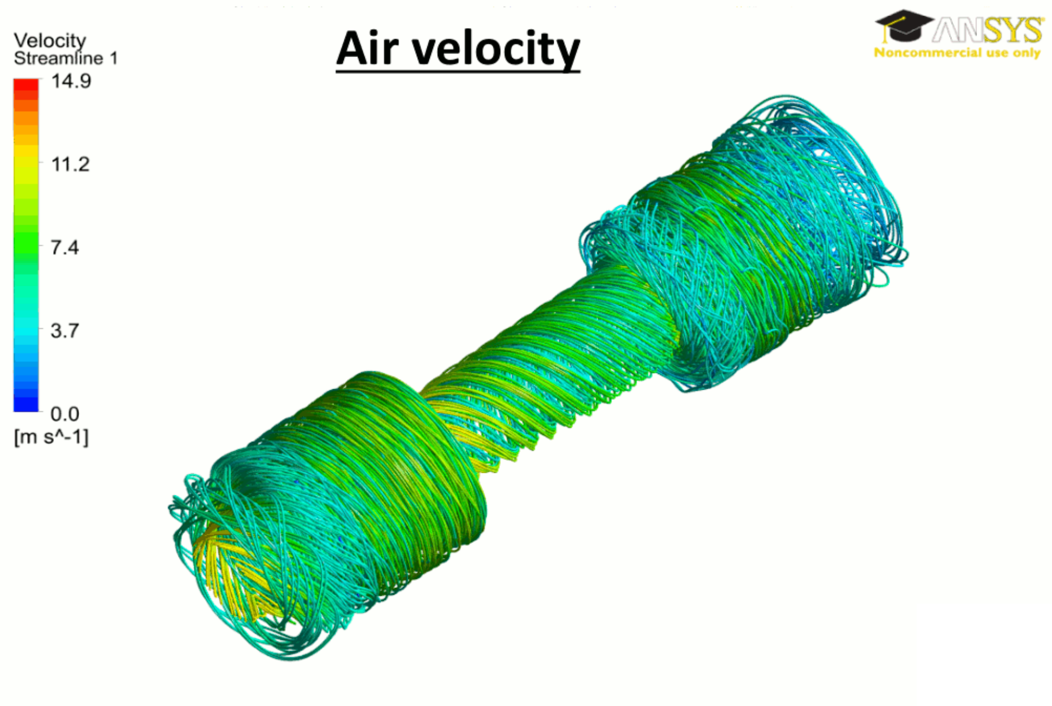
(including safety factors of 5)

Vertex detector cooling

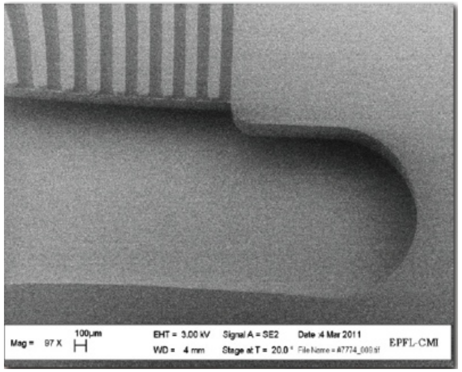
Vertex detector: P ≈ 500 W → need low mass cooling solutions

Forced (dry) air flow:
- Baseline for barrel region
- No extra material
- FEM studies show encouraging first results

Options in forward disks:
- Evaporative CO_2 cooling (high pressure → thick tubes)
- Water cooling (sub-atmospheric pressure)



Micro-channel cooling:
- Ongoing R&D (e.g. NA62 upgrade)
- Integrate cooling channels in Silicon
- May be suitable for regions with insufficient air flow

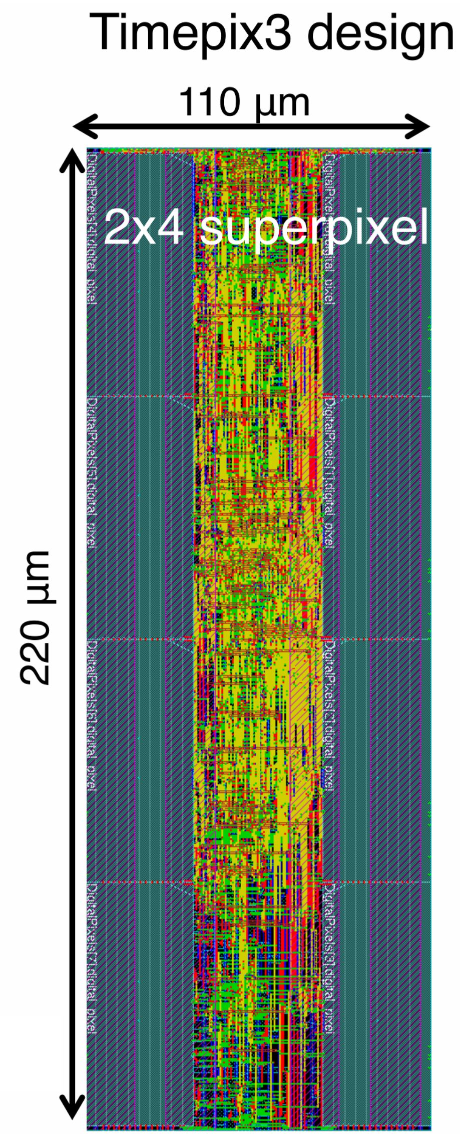


Pixel sensor options I

1.) **Hybrid technologies**:
- Thinned high-resistivity fully depleted sensors
- Fast, low-power highly integrated readout chip
- Low mass interconnects

Pros: - Factorisation of sensor + readout R&D
→ Readout chips profit fully from advancing industry standards

Cons: - Interconnect difficult / expensive → needs R&D
- Harder to reduce material



- **Thinned high-resistivity fully depleted sensors:**
  - 50 µm active thickness
  - ALICE pixel upgrade → meets CLIC goals
- **Fast low-power readout chips:**
  - Timepix3 (≈2013) in 130 nm IBM CMOS:
    - 55 x 55 µm^2 pixels
    - 1.5 ns time resolution → exceeds CLIC goals
    - P ≈ 10 µW / pixel
  - CLICPix (≈2015) in 65 nm, 20 x 20 µm^2 pixels
  - CLICPix demonstrator prototypes (≈2013): 64x64 pixel array

Pixel sensor options II

2.) **Integrated technologies**:

- Sensor and readout combined in one chip
- Charge collection in epitaxial layer

Pros: - Allows for very low material solutions
- Synergy with R&D for ILC detectors

Cons: - Harder to achieve good time resolution and sufficient S/N

- Several active R&D programs (targeted to ILC requirements)
- Attempts to reach faster signal collection and ns time-stamping capability (compatible with CLIC requirements):
  - MIMOSA CMOS with high-resistivity epitaxial layers
  - Chronopixel CMOS
  - INMAPS
  - High voltage CMOS

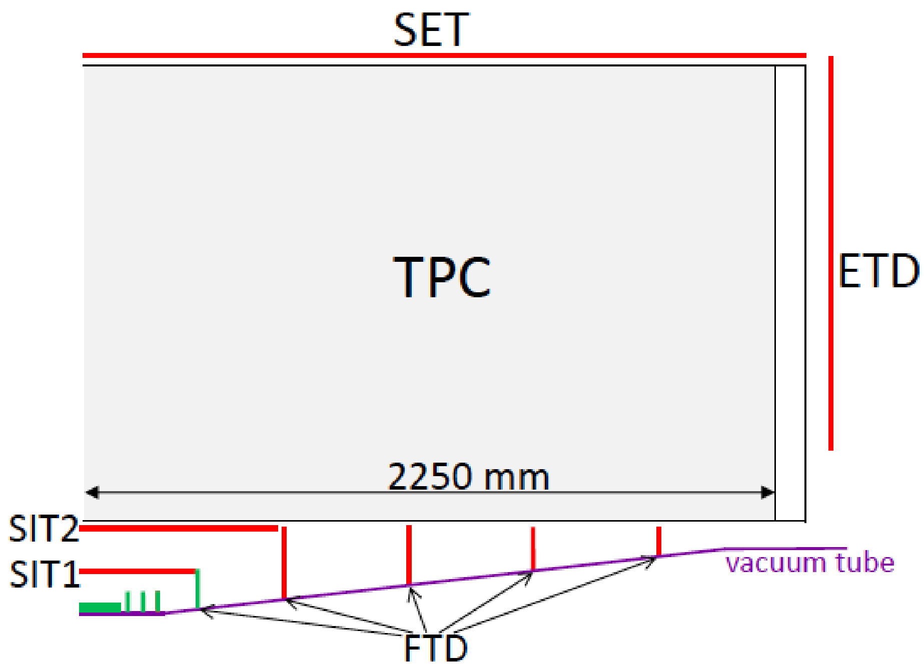
3.) **New technologies**:

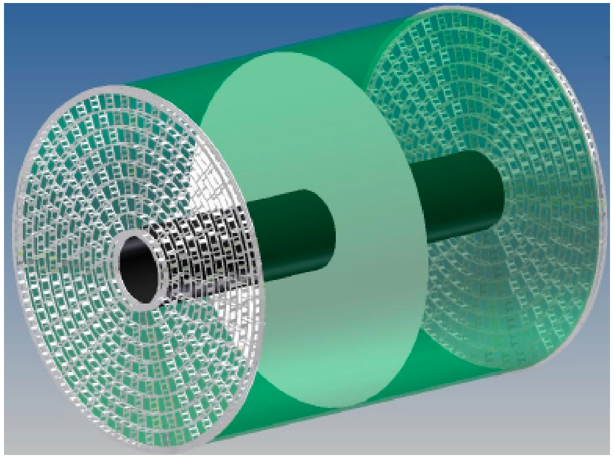
- Silicon-On-Insulator (SOI)
- Full 3D-integrated pixel sensors

Tracking

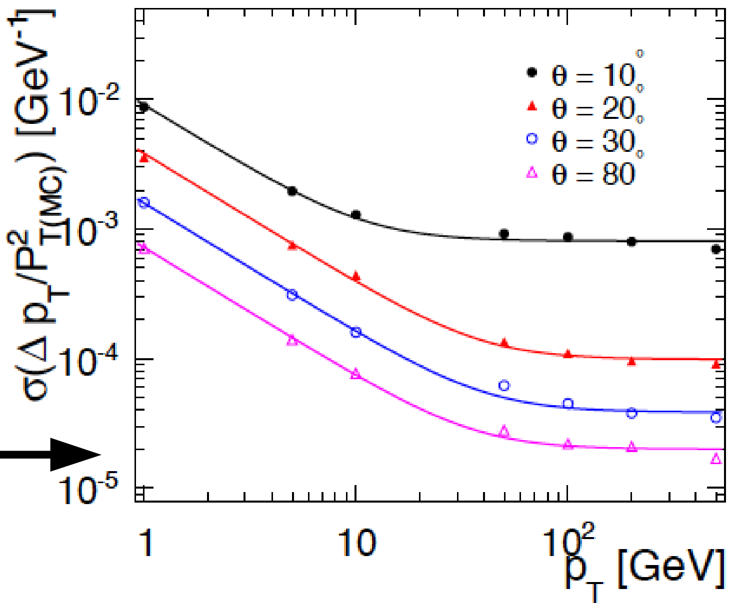
Tracking in CLIC_ILD

TPC + silicon tracking in 4T field





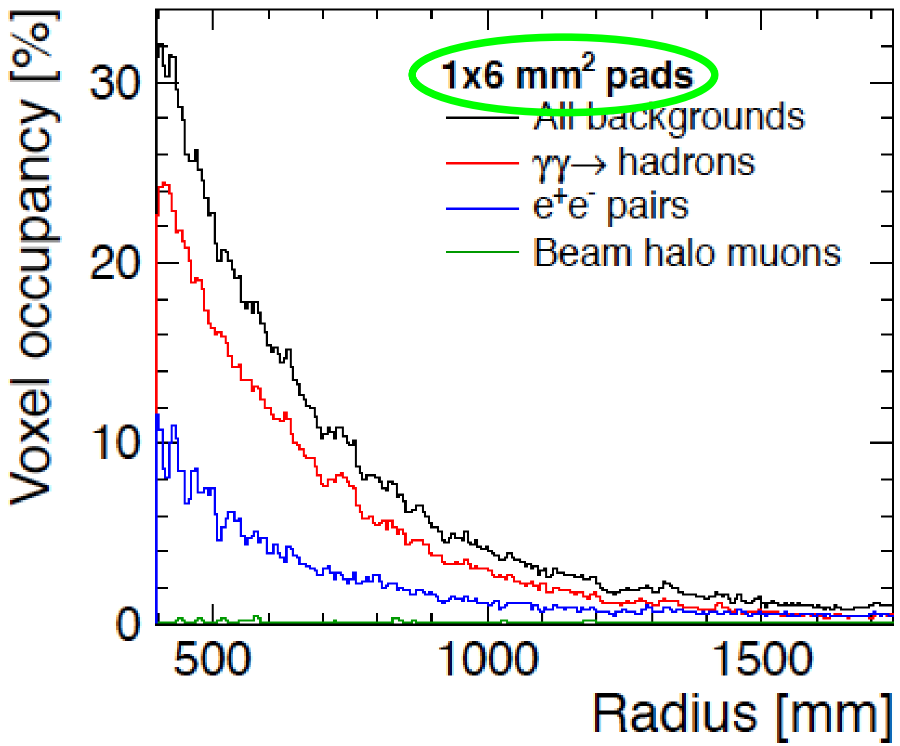
Time projection chamber (TPC)

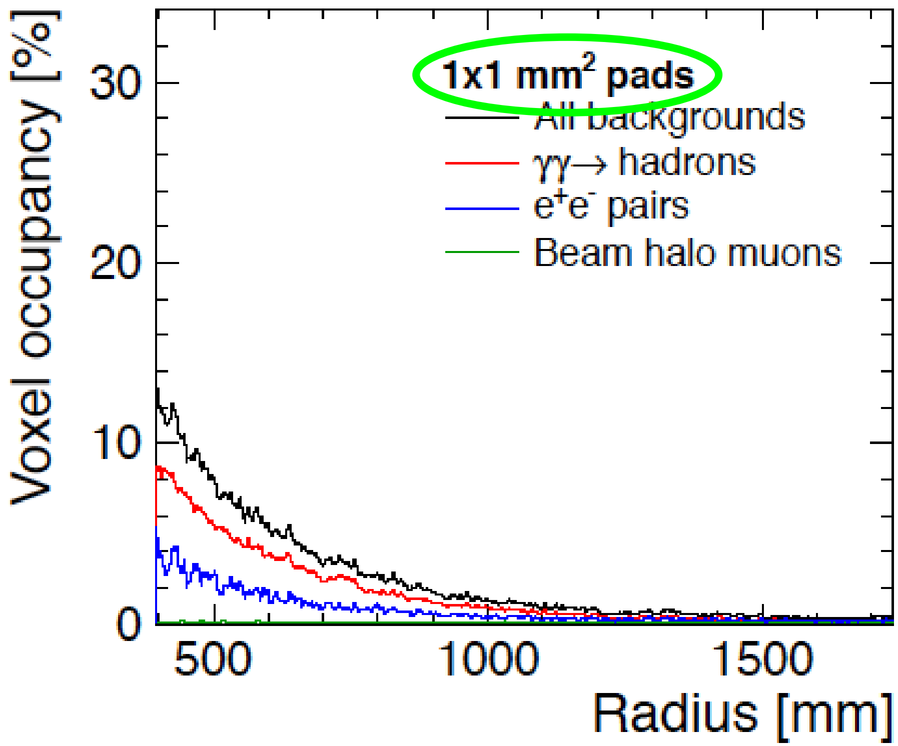


Performance goal on momentum resolution achieved

Occupancies in the TPC

The readout time of the TPC is much longer than a CLIC bunch train
→ The TPC integrates the background of a full train at CLIC



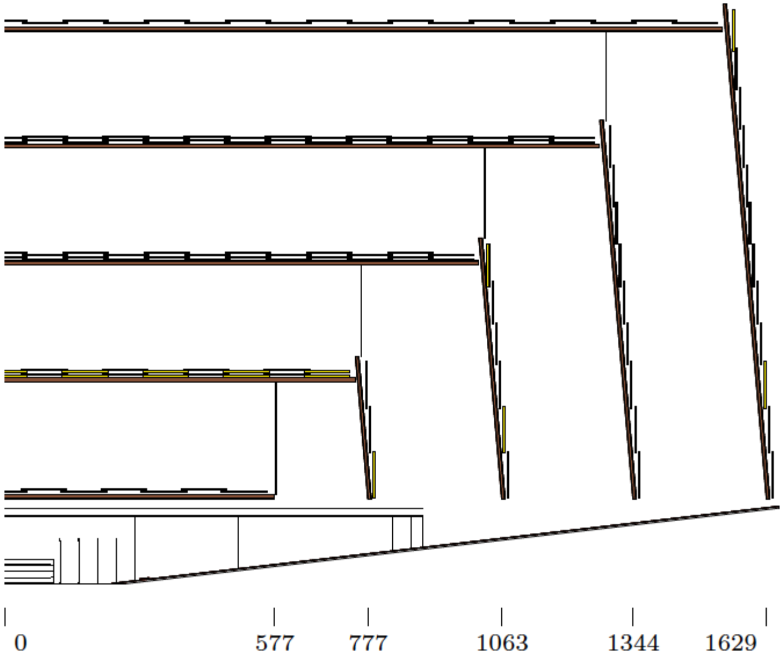


Plots are for Gas Electron Multiplier (GEM) + Pad readout, voxels of 25 ns

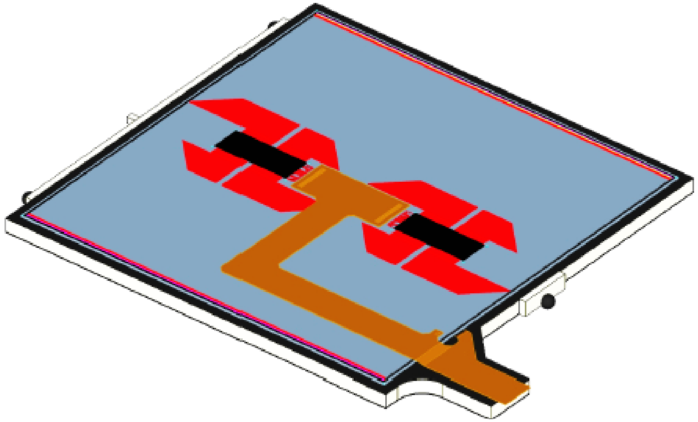
→ A TPC at CLIC may need a larger inner radius or very small pads
Similar study with micromegas + pixel readout is starting

Tracking in CLIC_SiD

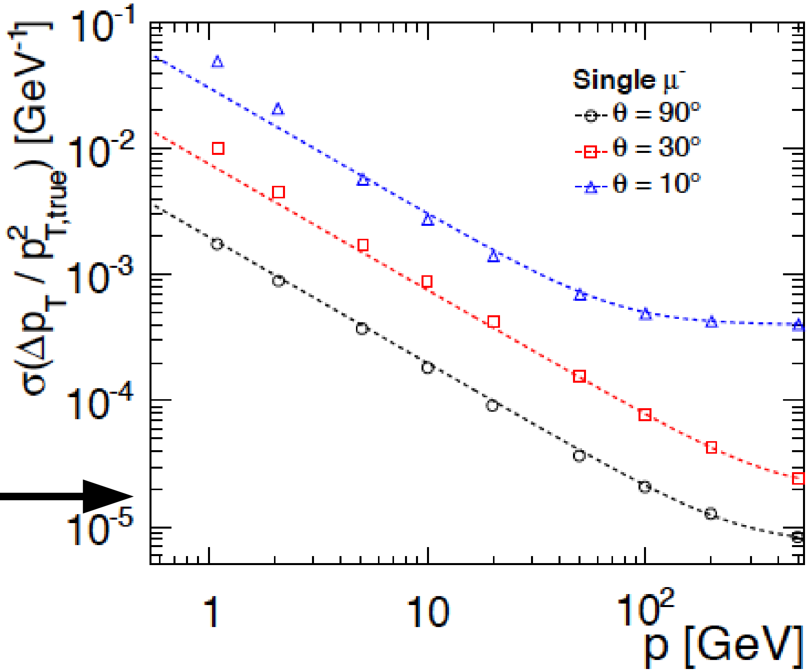
All silicon tracker in 5T field:
- Vertex detector and tracker viewed as one system
- Combined seeding and tracking



Two readout (KPiX) chips bump bonded to the sensor



Performance goal on momentum resolution achieved



Calorimetry

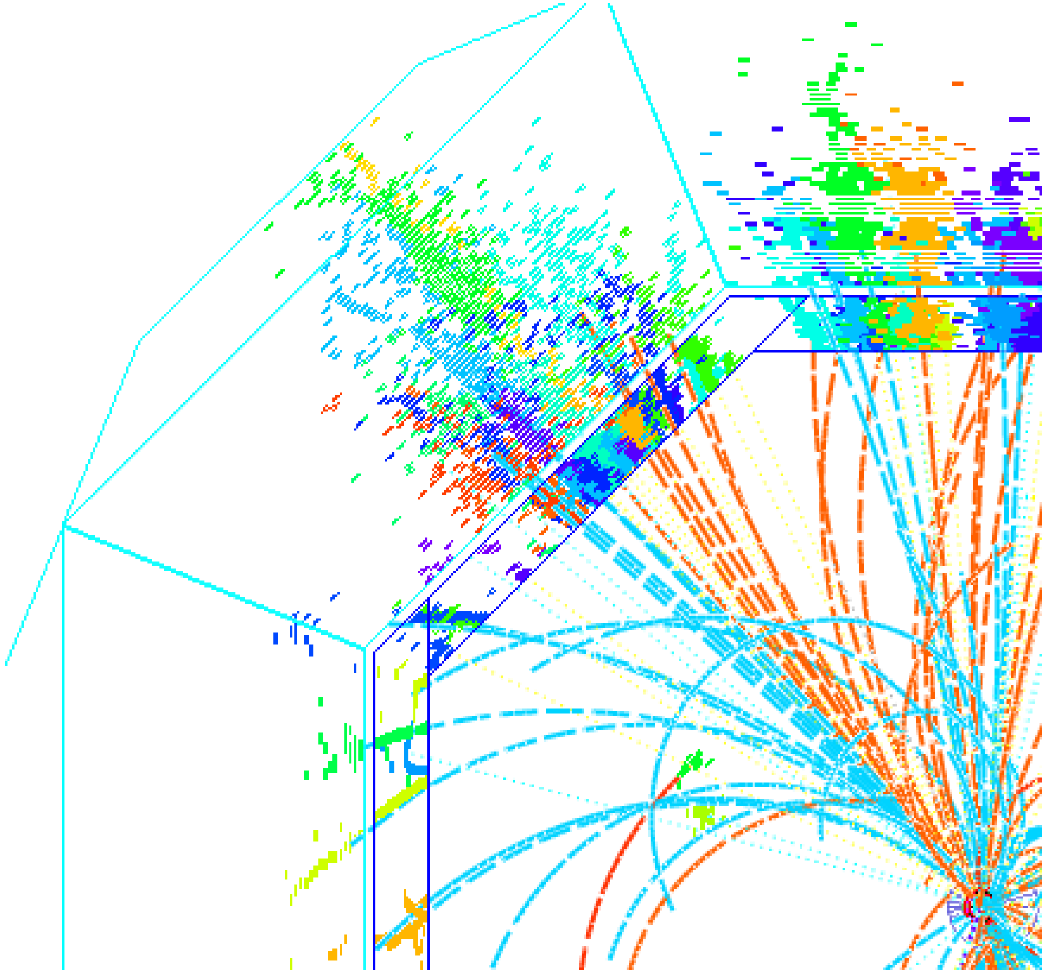
Calorimetry and PFA

Detector design driven by jet energy resolution and background rejection
→ Fine-grained calorimetry + particle flow analysis (PFA)

What is PFA?
Typical jet composition:
- 60% charged particles
- 30% photons
- 10% neutral hadrons

Always use the best available measurement:
- charged particles
→ tracking detectors:
- photons → ECAL:
- neutrals → HCAL:

Hardware and software!



Calorimetry: technology

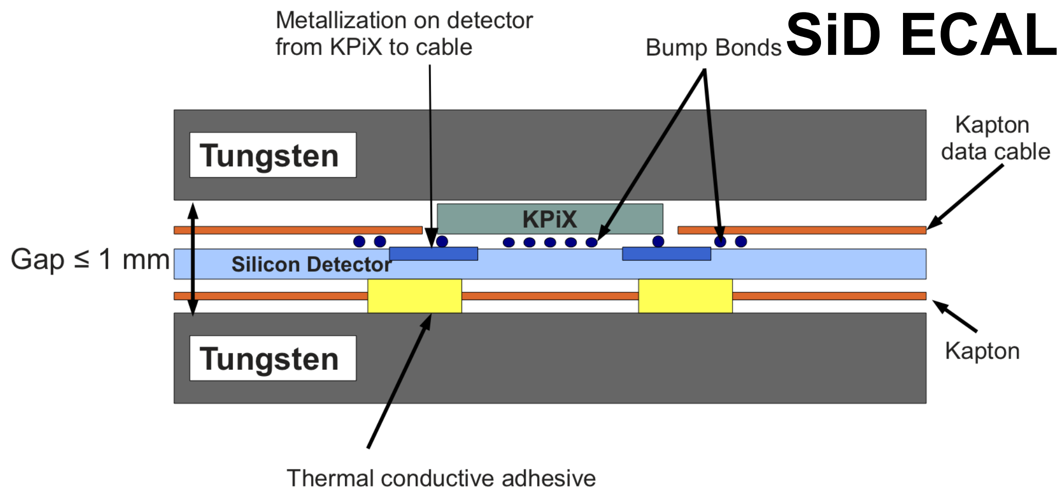
ECAL:

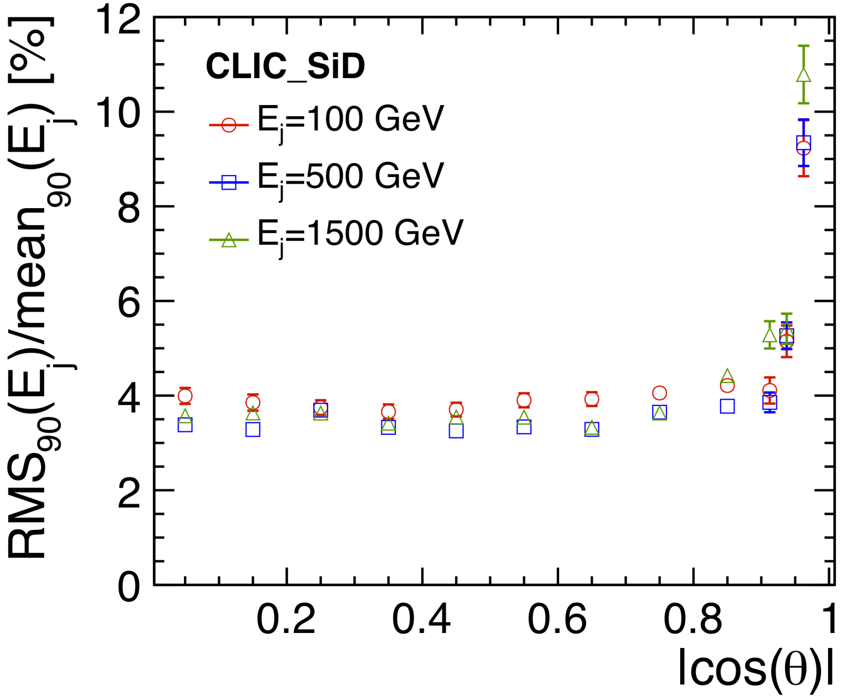
- Silicon pads or scintillator
- Tungsten absorber
- Cell sizes: 25 mm^2 (CLIC_ILD)
  13 mm^2 (CLIC_SiD)
- 30 layers in depth
- 23 X_0 and 1 λ

HCAL:

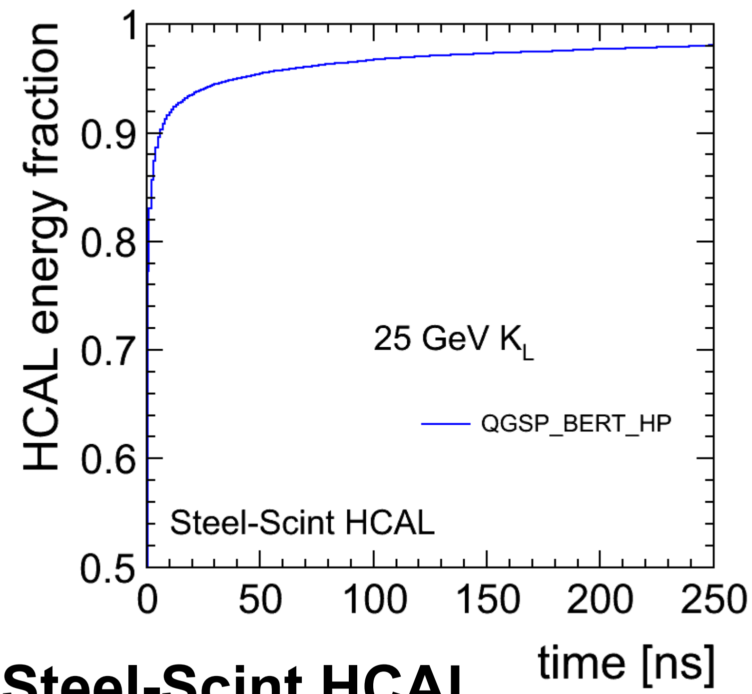
- Several options for sensors
- Tungsten (barrel), steel (forward)
- Cell sizes: 9 cm^2 (analog)
  1 cm^2 (digital)
- 60 - 75 layers in depth
- 7.5 λ

SiD ECAL

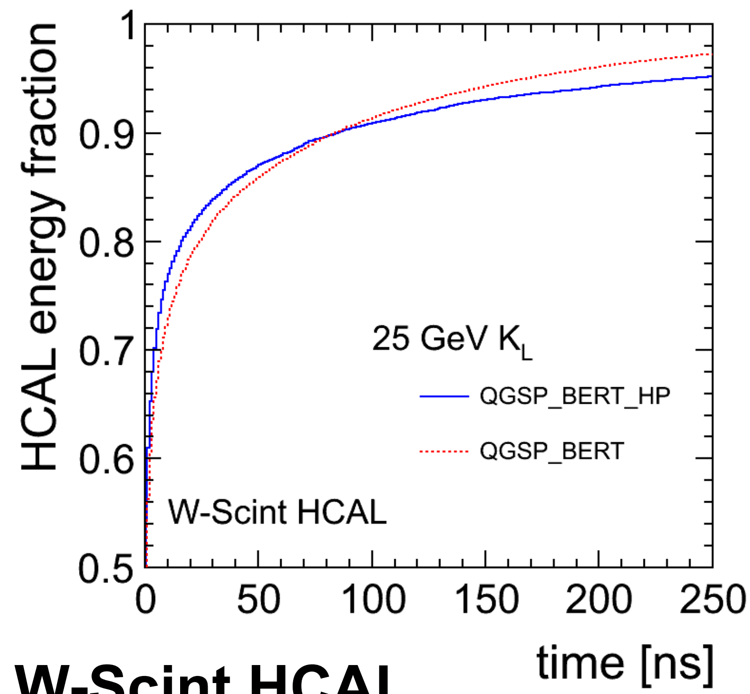




Time development in hadronic showers



Steel-Scint HCAL



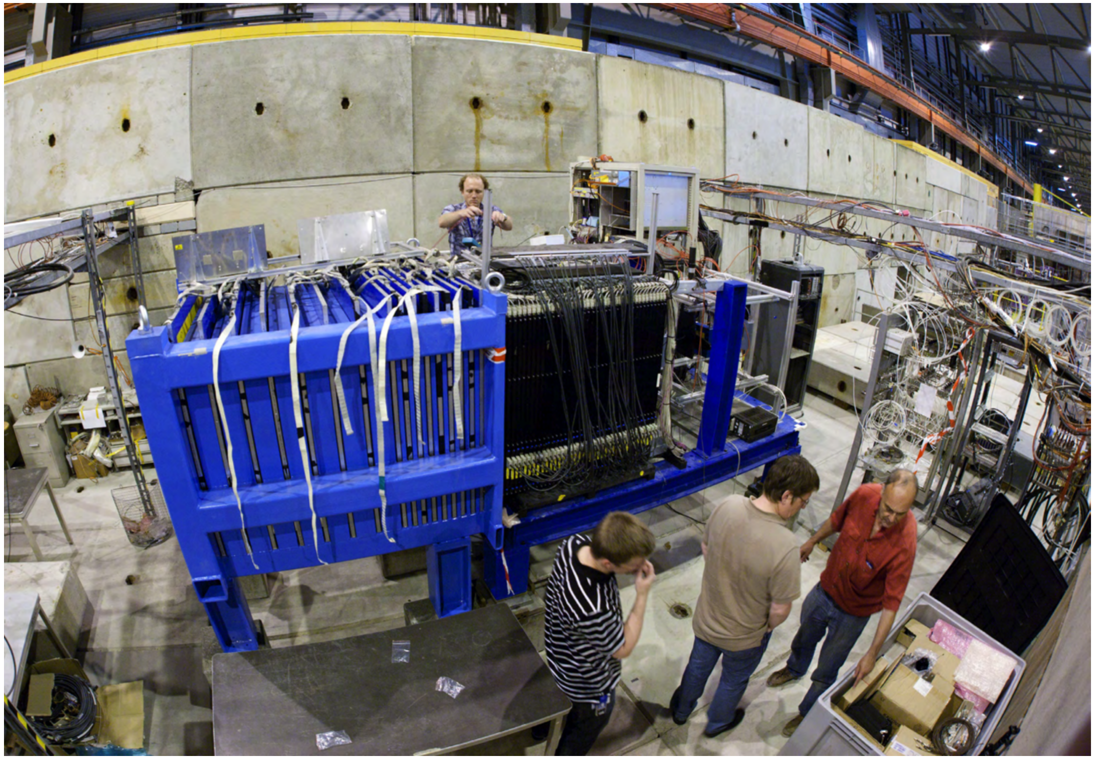
W-Scint HCAL

• In steel 90% of the energy is recorded within 6 ns (corrected for time-of-flight)
• In tungsten only 82% of the energy is deposited within 25 ns:
(much larger component of the energy in nuclear fragments)
→ Energy resolution degrades if not the majority of calorimeter hits is read

→ Need to integrate over ≈100 ns in the reconstruction, keeping the background level low

Test beam measurements using tungsten absorbers

Main purpose: Validation of Geant4 simulation for hadronic showers in tungsten



CERN-PS & SPS,
mixed beams 1-300 GeV

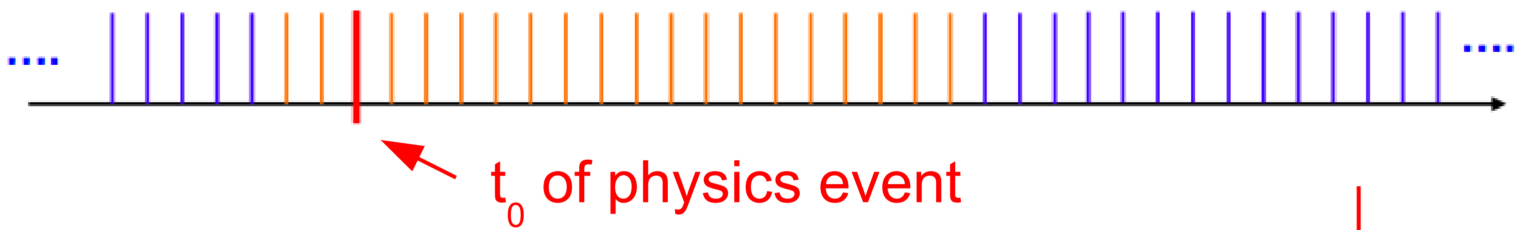
2010 & 2011:
Analog readout:
- Scintillator tiles 3x3 cm^2
- Read out by SiPM

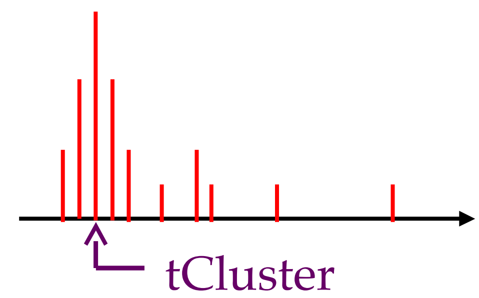
2012 (ongoing):
Digital (1-bit) readout:
- RPCs as active medium
- Fine segmentation with 1x1 cm^2 pads

Background suppression and event reconstruction

Background suppression

Triggerless readout of full bunch train:





1.) **Identify t_0 of physics event in offline event filter**
- Define reconstruction window around t_0
- All hits and tracks in this window are passed to the reconstruction

→ Physics objects with precise p_T and cluster time information

2.) **Apply cluster-based timing cuts**
- Cuts depend on particle-type, p_T and detector region

→ Protects physics objects at high p_T

Time windows and hit resolutions

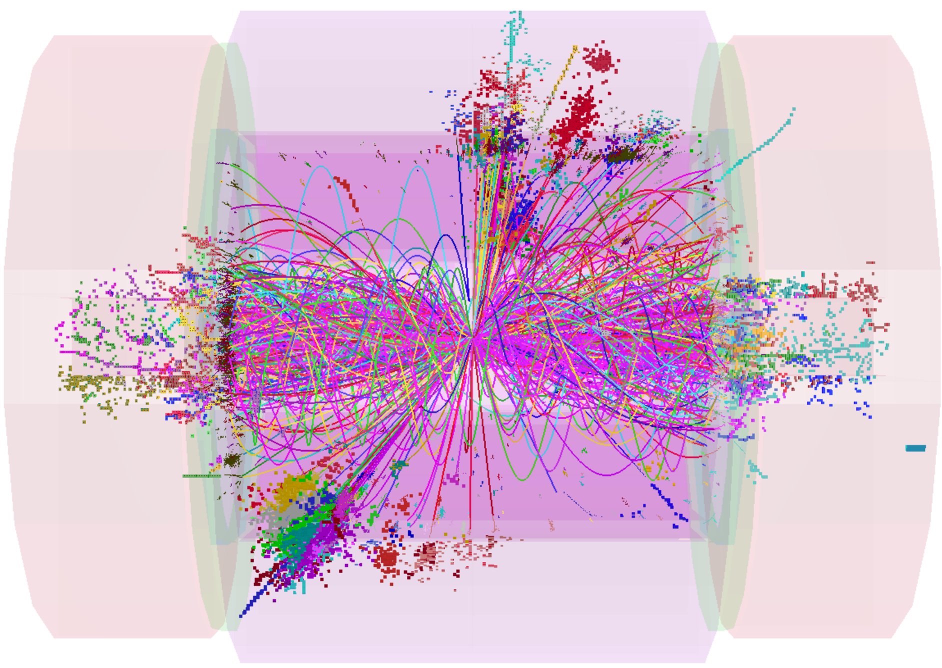
Used in the reconstruction software for CDR simulations:

Subdetector	Reconstruction window	hit resolution
ECAL	10 ns	1 ns
HCAL Endcaps	10 ns	1 ns
HCAL Barrel	100 ns	1 ns
Silicon Detectors	10 ns	$10/\sqrt{12}$ ns
TPC	entire bunch train	n/a

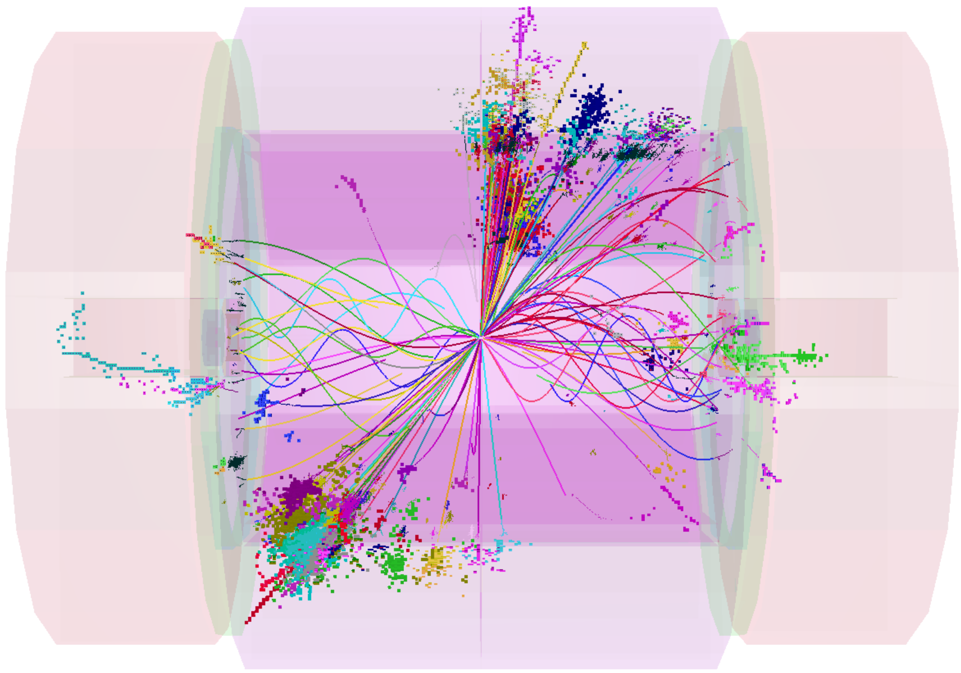
- CLIC hardware requirements
- Achievable in the calorimeters with a sampling every ≈ 25 ns

Impact of the timing cuts

$e^+e^- \rightarrow H^+H^- \rightarrow t\bar{b}b\bar{t}$ (8 jet final state)

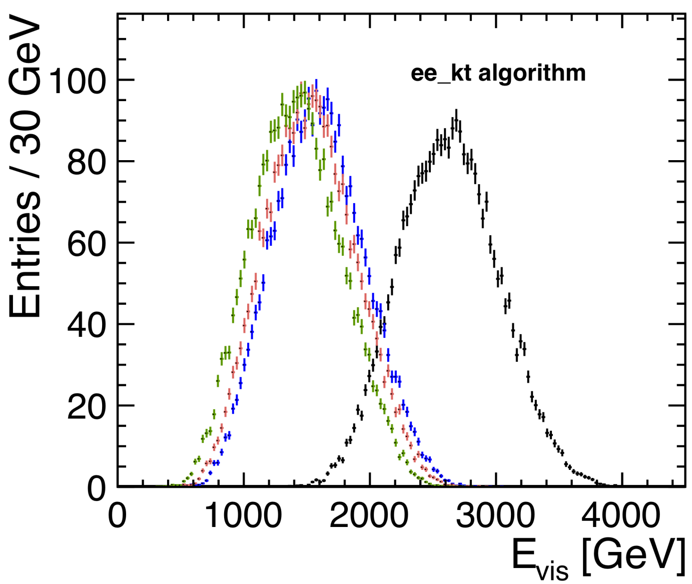


1.2 TeV background
in the reconstruction window



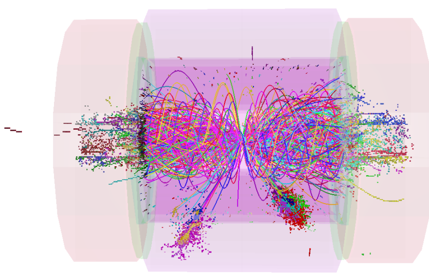
100 GeV background
after (tight) timing cuts

Jet reconstruction at CLIC I

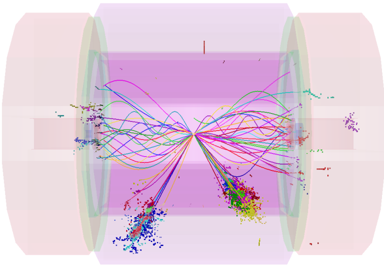


$$e^+e^- \rightarrow \tilde{q}_R\tilde{q}_R \rightarrow q\bar{q}\,\tilde{\chi}_1^0\,\tilde{\chi}_1^0$$

Two jets + missing energy



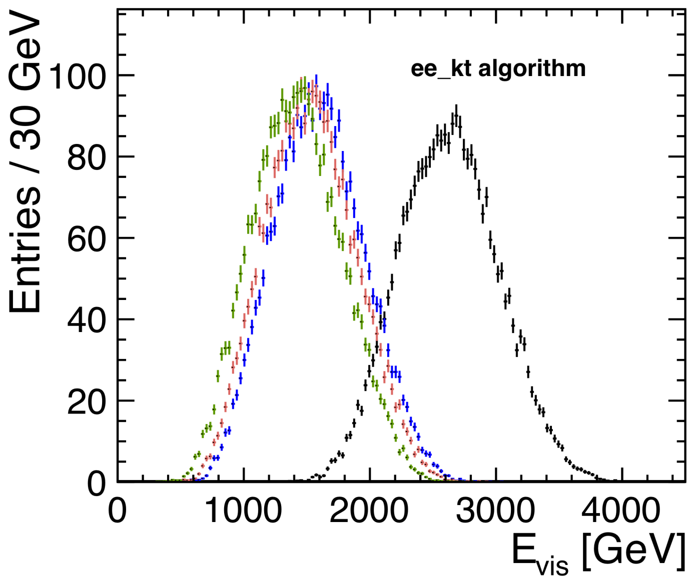
Timing cuts

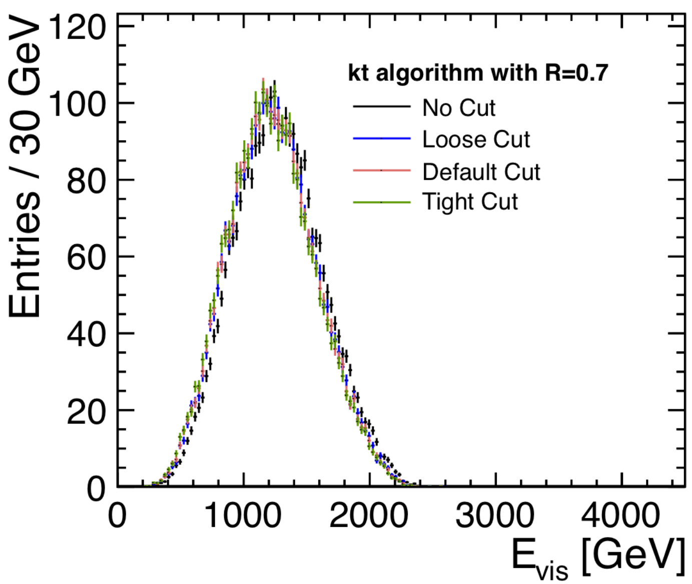


- Using Durham k_T à la LEP

→ Timing cuts are effective, but not sufficient

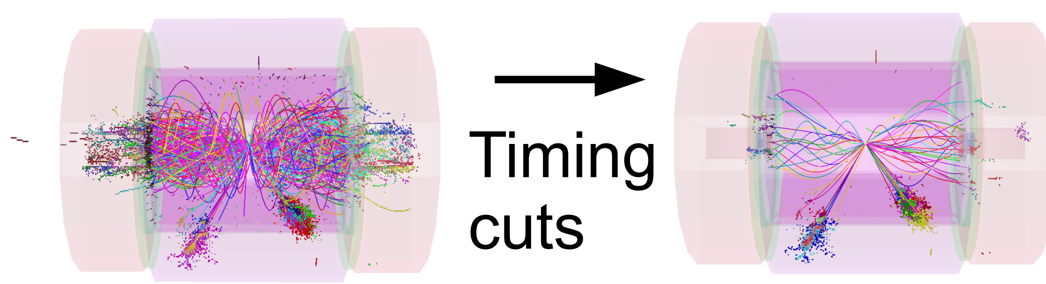
Jet reconstruction at CLIC II





$$e^+e^- \rightarrow \tilde{q}_R\tilde{q}_R \rightarrow q\bar{q}\,\tilde{\chi}_1^0\,\tilde{\chi}_1^0$$

Two jets + missing energy



- Using Durham k_T à la LEP

$\rightarrow$ Timing cuts are effective, but not sufficient

- "hadron collider" k_T, R = 0.7

$\rightarrow$ Background significantly reduced further

$\rightarrow$ Need timing cut + jet finding for background reduction

Physics benchmark studies

Test of the di-jet mass reconstruction

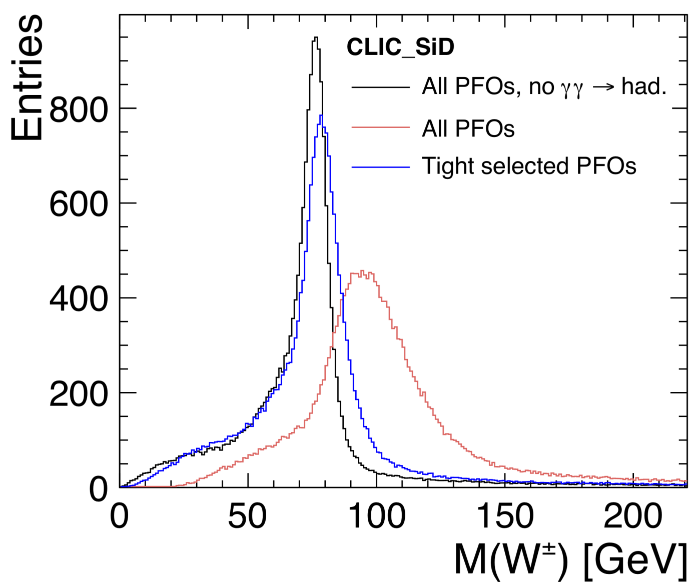
Chargino and neutralino pair production:

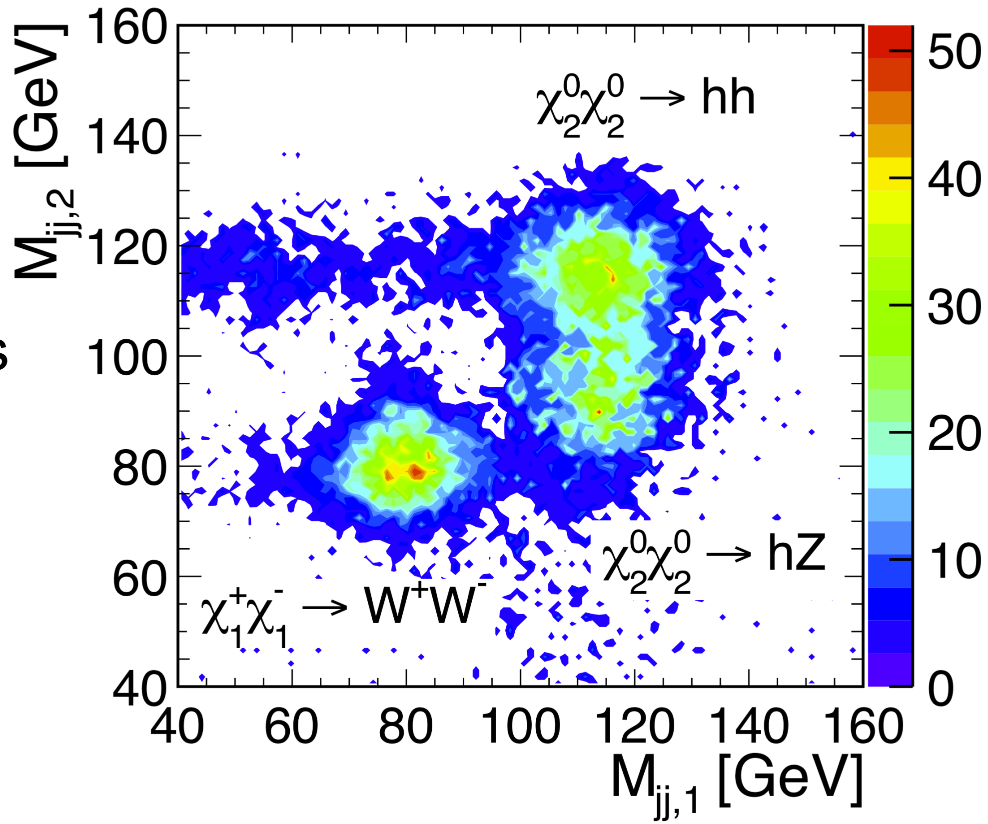
$$e^+e^- \rightarrow \tilde{\chi}_1^+\tilde{\chi}_1^- \rightarrow \tilde{\chi}_1^0\tilde{\chi}_1^0 W^+W^-$$

$$e^+e^- \rightarrow \tilde{\chi}_2^0\tilde{\chi}_2^0 \rightarrow hh\,\tilde{\chi}_1^0\tilde{\chi}_1^0 \qquad 82\%$$

$$e^+e^- \rightarrow \tilde{\chi}_2^0\tilde{\chi}_2^0 \rightarrow Zh\,\tilde{\chi}_1^0\tilde{\chi}_1^0 \qquad 17\%$$

Reconstruct $W^{\pm}$/Z/h in hadronic decays
→ four jets and missing energy



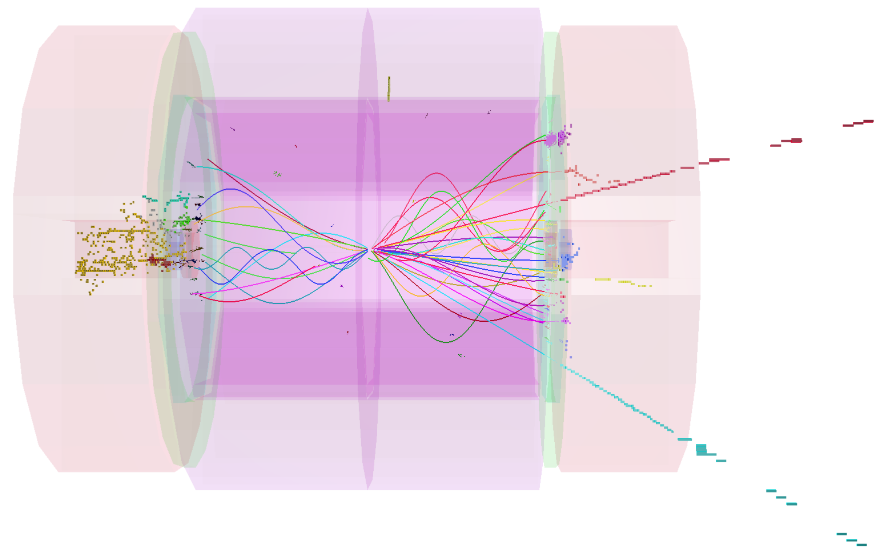


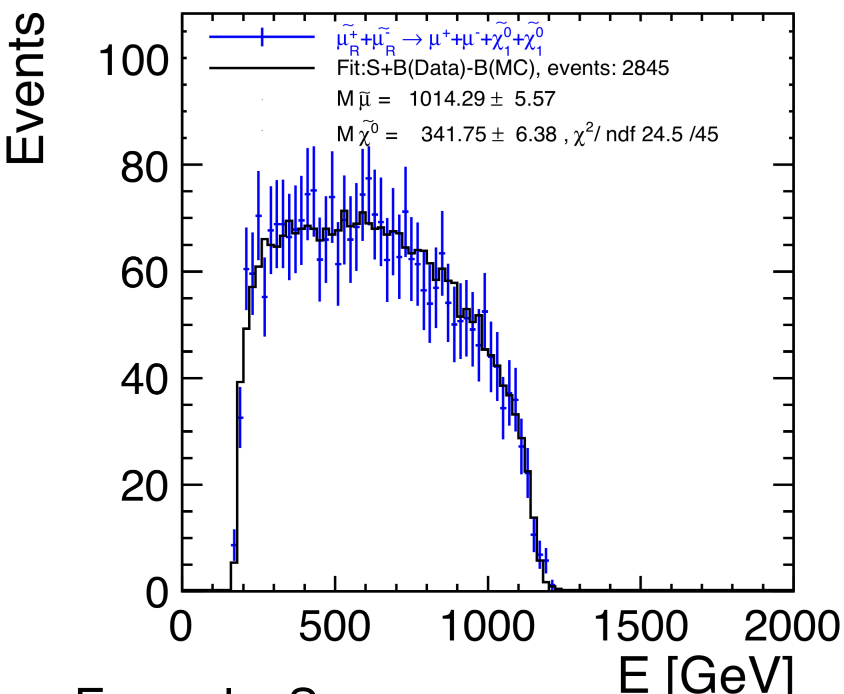
Precision on the measured gaugino masses (few hundred GeV): 1 - 1.5%

Test of the lepton reconstruction

- Slepton production very clean at CLIC
- SUSY "model II": slepton masses ≈ 1 TeV
- Investigated channels include:

$$e^+e^- \to \tilde{\mu}_R^+\tilde{\mu}_R^- \to \mu^+\mu^-\,\tilde{\chi}_1^0\,\tilde{\chi}_1^0$$
$$e^+e^- \to \tilde{e}_R^+\tilde{e}_R^- \to e^+e^-\,\tilde{\chi}_1^0\,\tilde{\chi}_1^0$$
$$e^+e^- \to \tilde{\nu}_e\tilde{\nu}_e \to e^+e^-W^+W^-\,\tilde{\chi}_1^0\,\tilde{\chi}_1^0$$





Example: Smuons

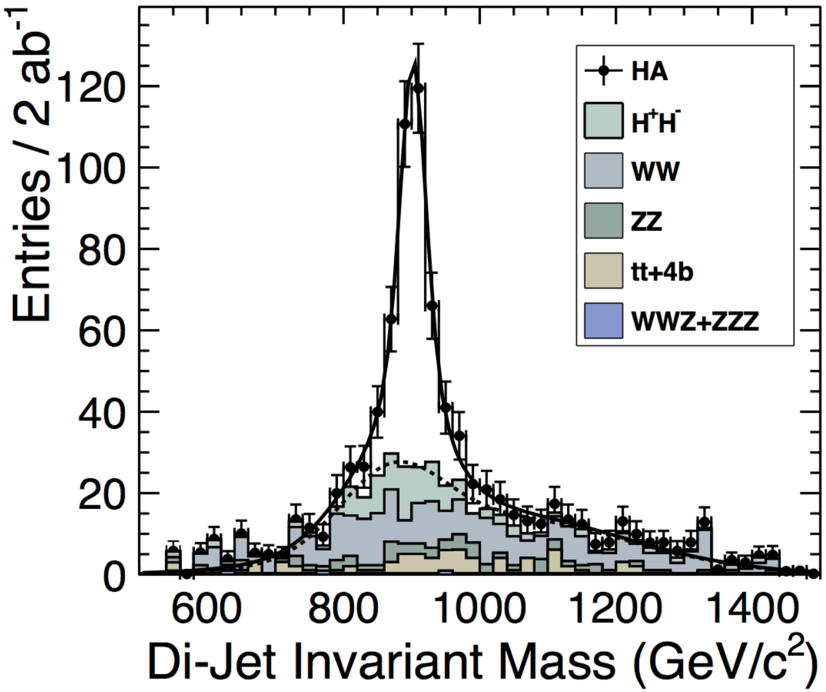
- Leptons and missing energy
- Masses from endpoints of energy spectra

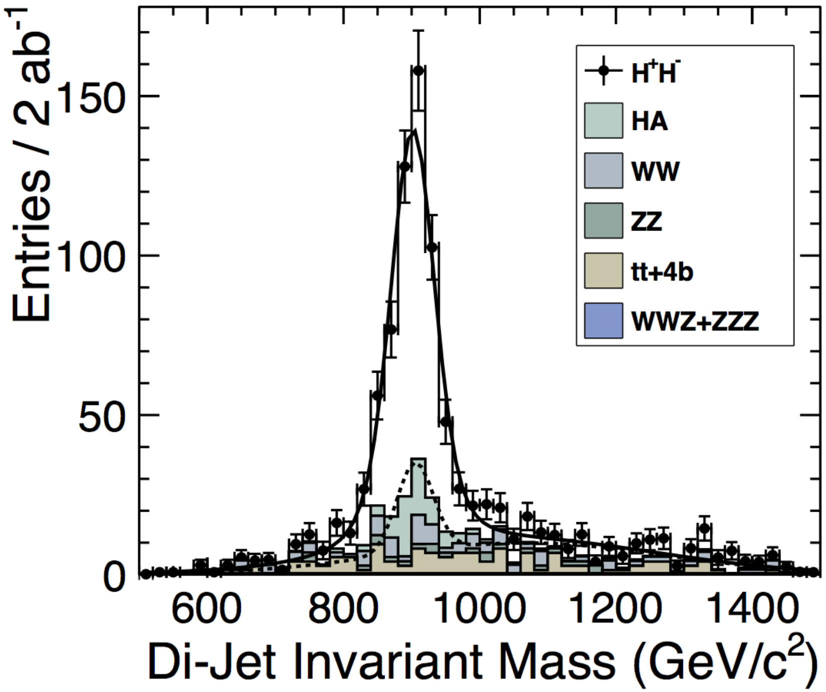
$m(\tilde{\mu}_R)$	± 5.6 GeV
$m(\tilde{e}_R)$	± 2.8 GeV
$m(\tilde{\nu}_e)$	± 3.9 GeV
$m(\tilde{\chi}_1^0)$	± 3.0 GeV
$m(\tilde{\chi}_1^\pm)$	± 3.7 GeV

Complex final states

Heavy Higgs bosons:
$e^+e^- \to HA \to b\bar{b}b\bar{b}$
$e^+e^- \to H^+H^- \to t\bar{b}b\bar{t}$

Flavour tagging crucial!





Accuracy of the heavy Higgs mass measurements: ≈ 0.3%

More detector benchmarks

- Full physics simulation and reconstruction with pileup from beam background ($\gamma\gamma \rightarrow$ hadr.)

- Seven channels chosen to cover various crucial aspects of detector performance (jet measurements, missing energy, isolated leptons, flavour tagging, ...)

CLIC energy staging

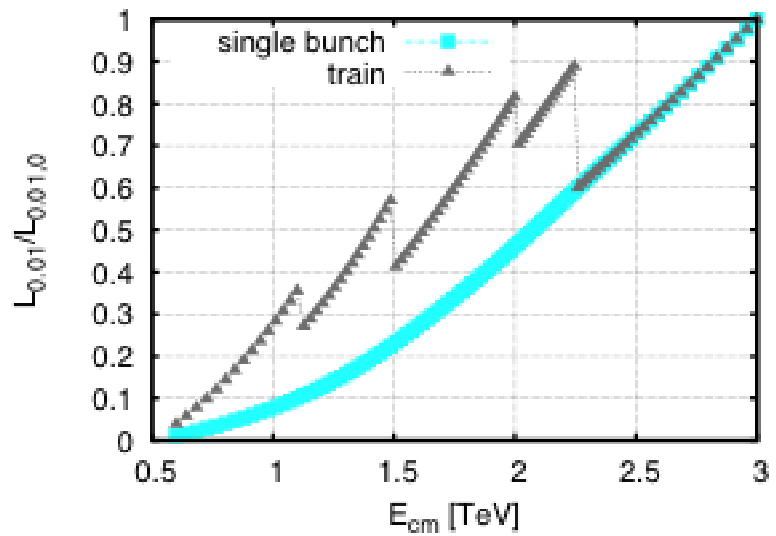
CLIC energy staging

Majority of CDR studies done at 3 TeV:
- Most challenging beam-induced backgrounds in the detectors
- Ultimate physics reach

Interesting physics (may) exist at various energies:
- Few 100 GeV:

Precision SM measurements: Higgs, top,...
- Still unknown:

Beyond Standard Model physics, potentially various thresholds from few 100 GeV to few TeV
→ Both require high luminosities!



- Significant luminosity penalty when running far below the nominal energy

- Possibility to start physics during construction phase for higher energies

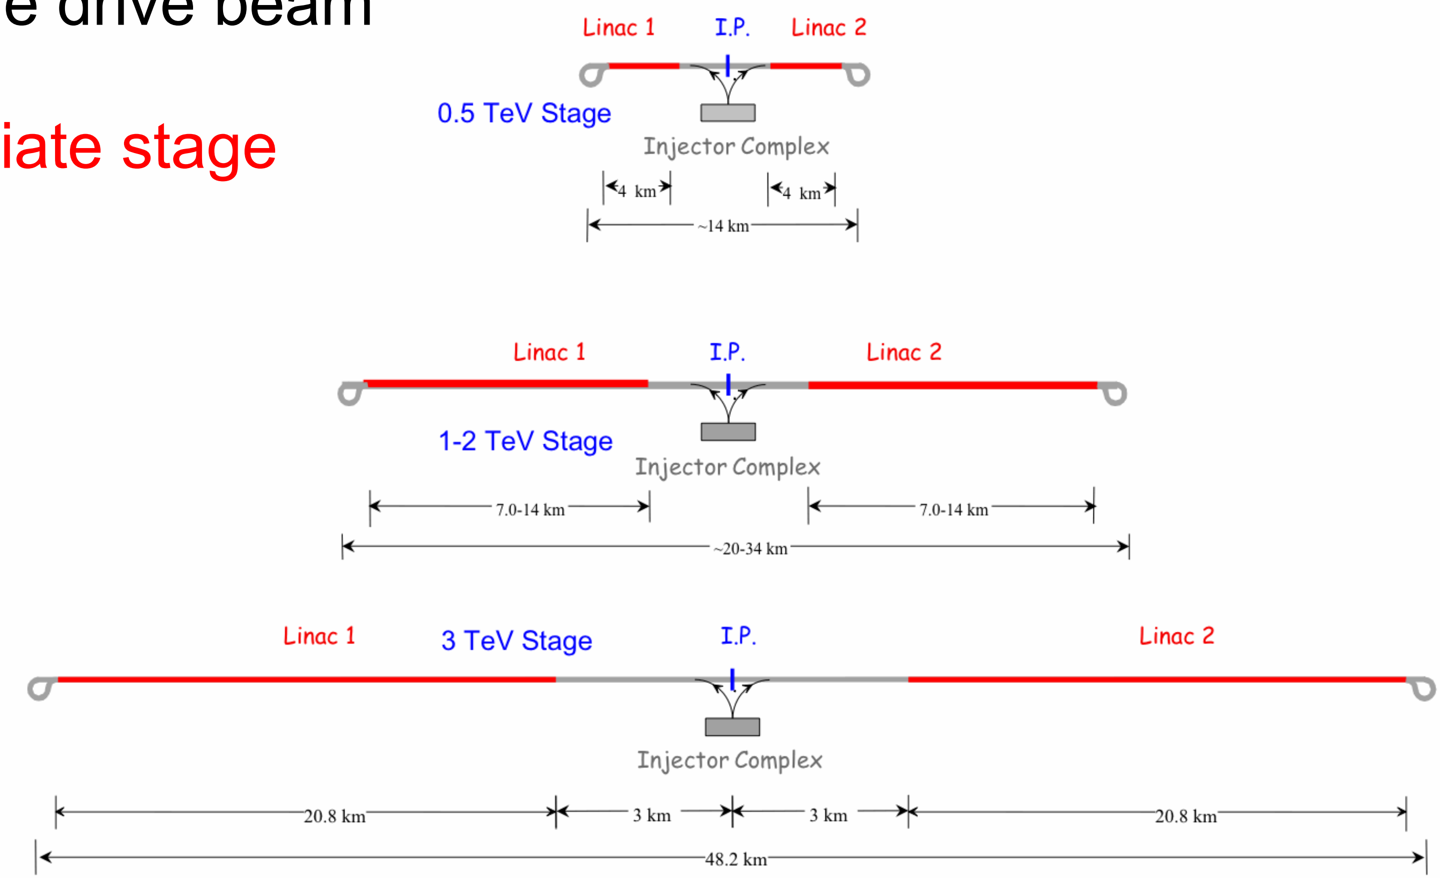
A possible scenario

Three energy stages:

• Exact energies to be determined by future results

• At 1.4 TeV only one drive beam complex needed

→ Natural intermediate stage



Ongoing benchmark studies for the CLIC CDR Vol. 3

Stage 1: E_{CMS} = 500 GeV, L = 500 fb^{-1}

- Top threshold scan (350 GeV)
- Higgs mass from ZH events (350 and 500 GeV)

Stage 2: E_{CMS} = 1400 GeV, L = 1.5 ab^{-1}

- Higgs self-coupling
- Several SUSY studies using a specific model

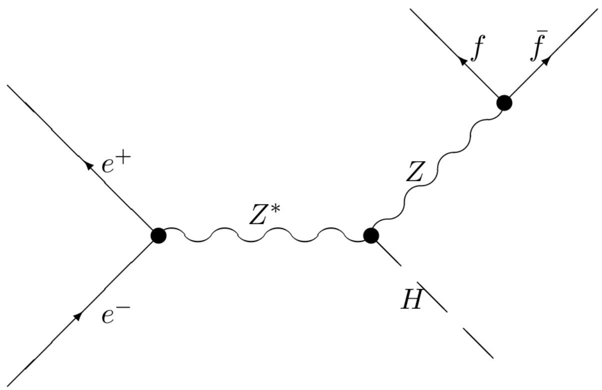
Stage 3: E_{CMS} = 3 TeV, L = 2 ab^{-1}

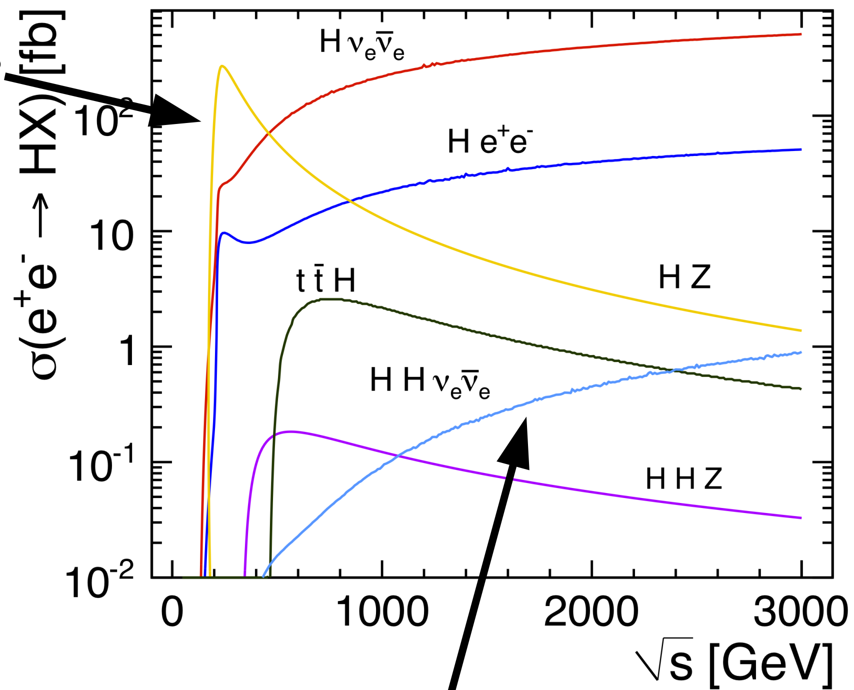
- Higgs self-coupling

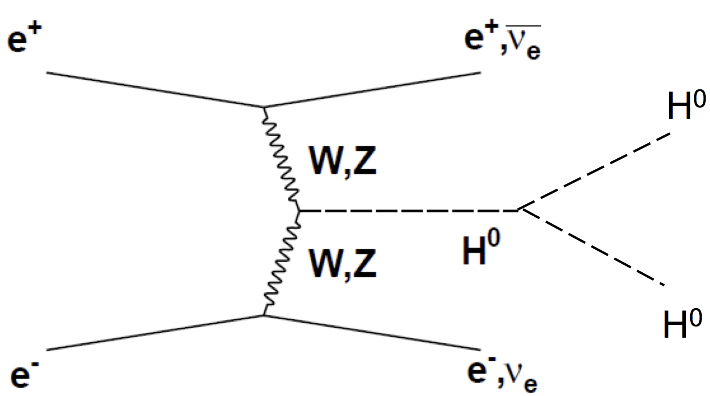
Higgs studies for Vol. 3

At 350 GeV and 500 GeV:

- Higgs mass and cross section from ZH events
- Measurement of Z recoil allows measurement without assumption on Higgs decay modes







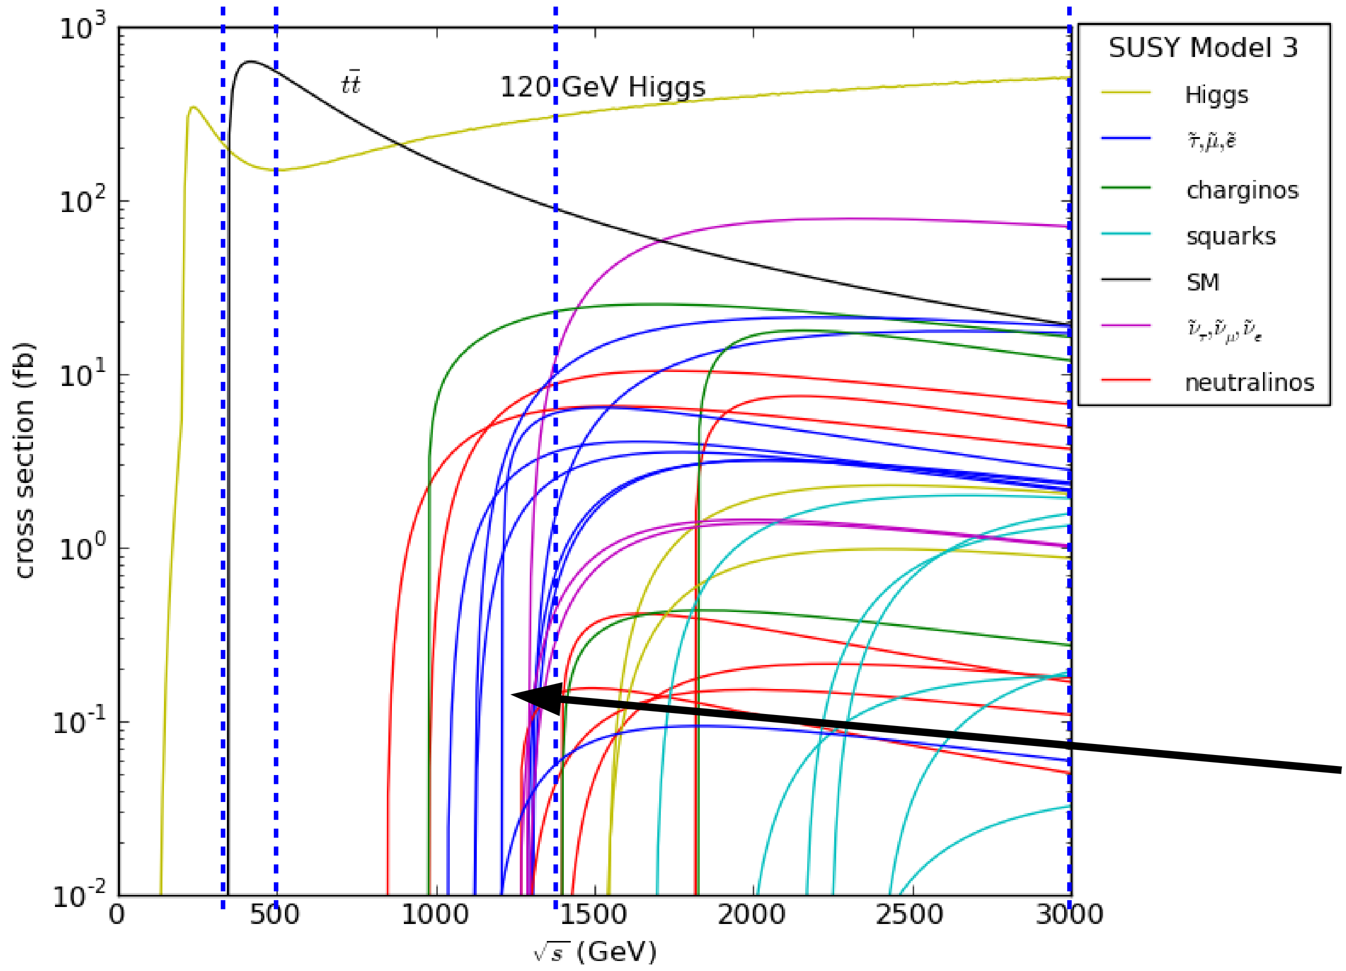
At 1.4 TeV and 3 TeV:

- Measure the HH final state

$\rightarrow$ allows extraction of the Higgs self-coupling

- Only possible at high energy (cross section)

SUSY model for staged energy studies



Stage 2:
- light gauginos
- sleptons
- squarks and charged Higgs too heavy

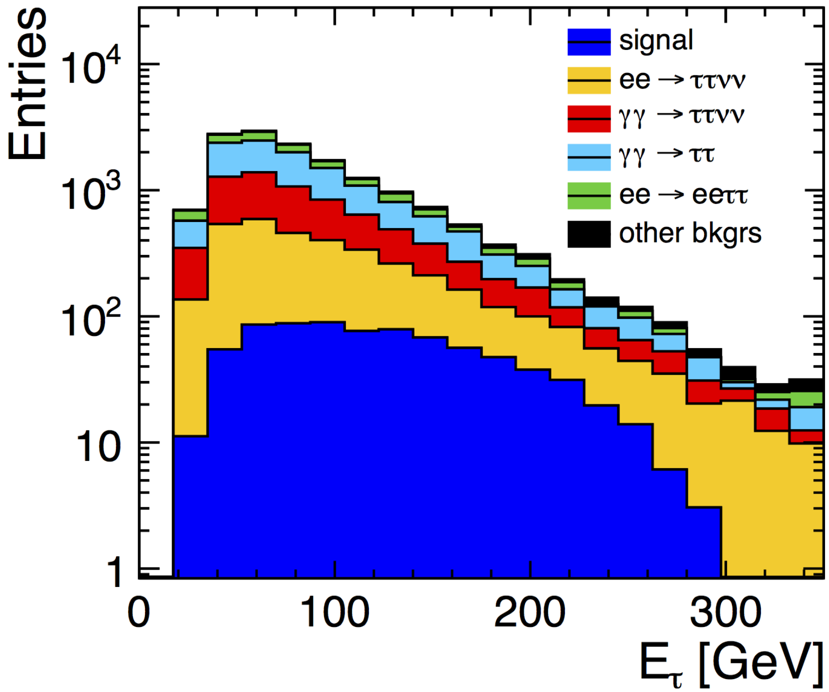
Quite different experimental challenges compared to the studies at 3 TeV, because SUSY particles produced close to threshold

Stau pair production

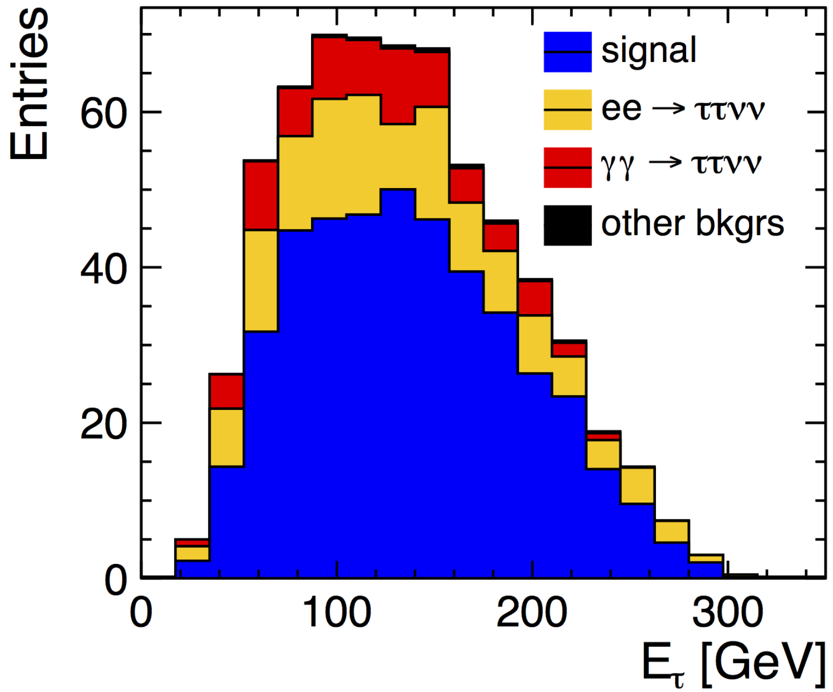
$$e^+ e^- \rightarrow \tilde{\tau}_1^+ \tilde{\tau}_1^- \rightarrow \tau^+ \tau^- \tilde{\chi}_1^0 \tilde{\chi}_1^0$$

$M(\tilde{\tau}_1^+) = 517$ GeV

Requires identification of tau leptons!



signal and backgrounds



selected candidates

Mass precision: ≈11 GeV

Beyond the CDR

Next phase: 2012 - 2016

Physics studies:
- Follow up on 8 TeV and 14 TeV LHC results
- Full exploration of SM physics potential (Higgs, top)
- More detailed understanding of reach for new physics
- Refinement of strategy for CLIC energy staging

Detector optimisation:
- General detector optimisation & simulation studies in close relation with detector R&D

Detector R&D:
- Implementation examples demonstrating the required functionality → see next slide
- Strong overlap with ILC detector R&D programme

Detector R&D

Vertex detector:
Demonstration module that meets the requirements

Main trackers:
Demonstration modules, including manageable occupancies in the event reconstruction

Calorimeters:
Demonstration modules, technological prototypes & cost mitigation

Electronics:
Demonstrators, in particular in view of power pulsing

Magnet systems:
Demonstrators of conductor technology, safety systems, etc.

Engineering and detector integration:
Engineering design and detector integration harmonised with hardware R&D demonstrators

→ **Considered feasible in a 5-year R&D program**

Summary and conclusions

Summary and conclusions

- Main message of the CLIC physics and detector CDR:
Physics at a 3 TeV CLIC e^+e^- collider can be measured with high precision, despite challenging background conditions

- Backgrounds studied in detail:
  - Require high granularity in space and time
  - Define detector requirements and guide future R&D

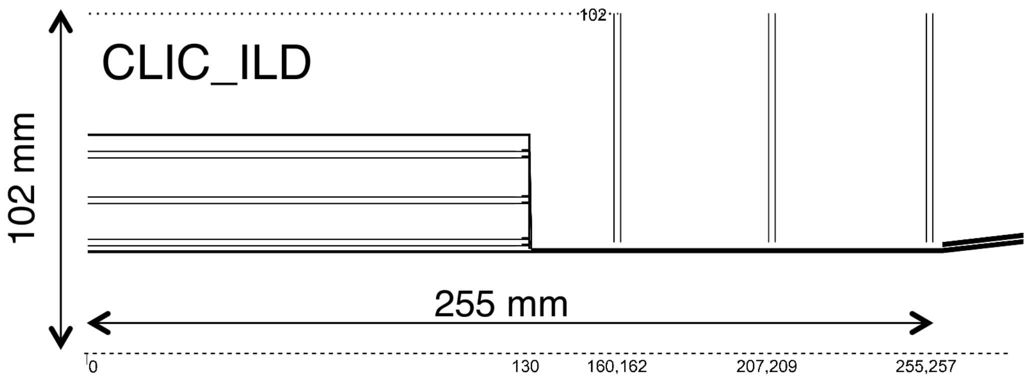
- The performance of the CLIC detector concepts was demonstrated using detector benchmark reactions

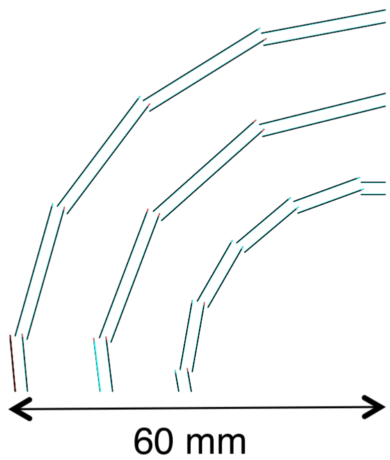
- Next project phase (5 years):
  - CLIC detector R&D (within the international LC R&D program)
  - Further physics studies (LHC input) + detector optimisation

Backup slides

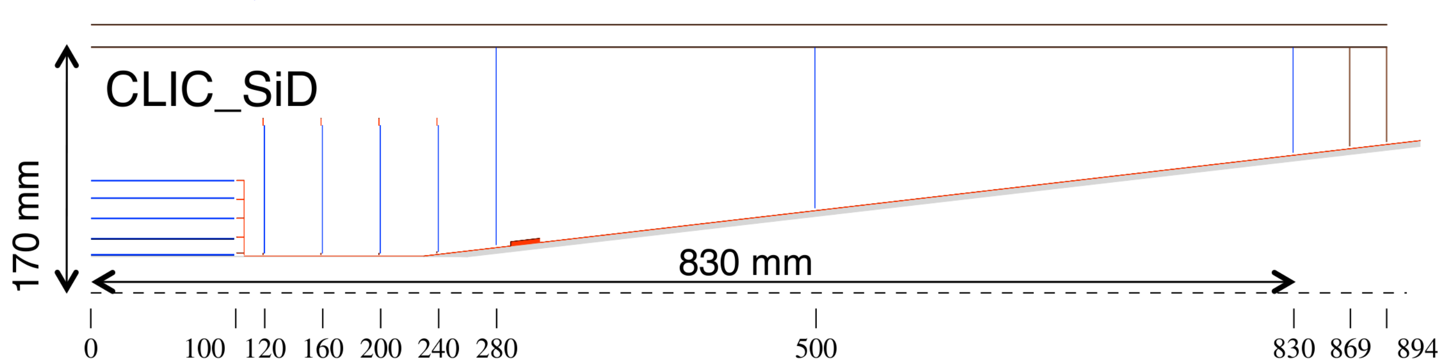
Vertex detector layouts

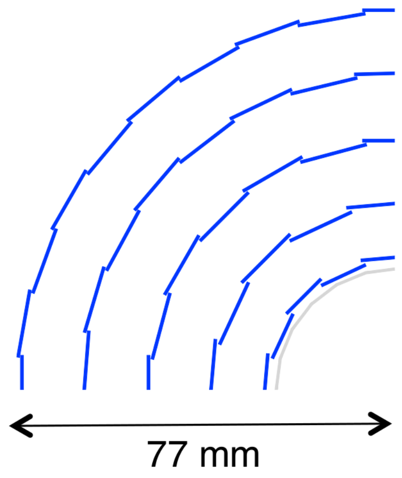
CLIC_ILD: 3 double layers, $1.84 \cdot 10^9$ pixels





CLIC_SiD: 5 single layers, $2.76 \cdot 10^9$ pixels



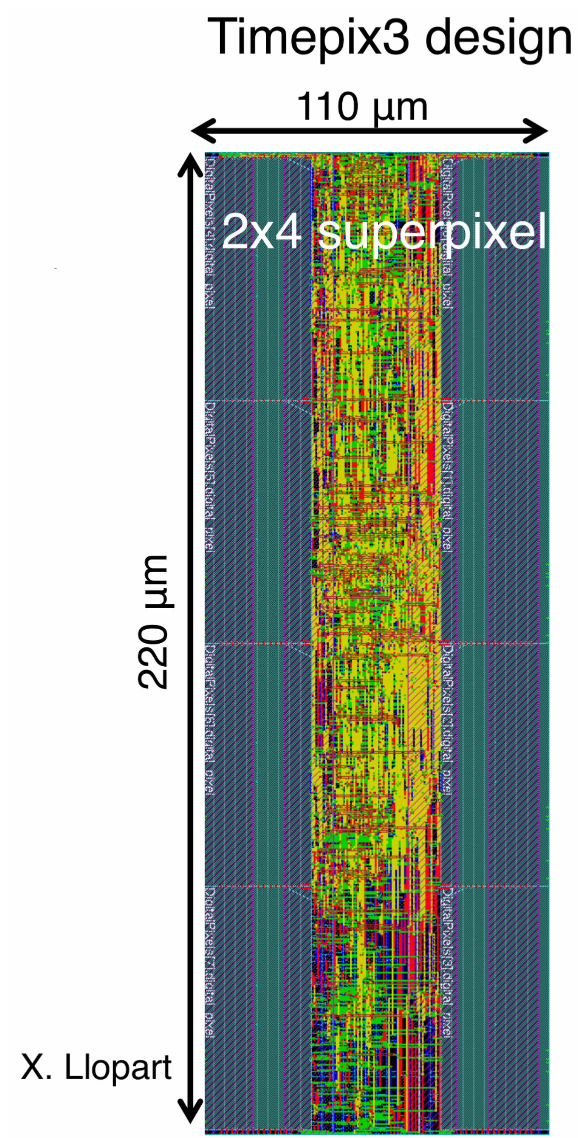


Examples for hybrid approach

Thinned high-resistivity fully depleted sensors:
- 50 µm active width
- Example: ALICE pixel upgrade → meets CLIC goals

Fast low-power readout chips:
- Timepix3 (2012) in 130 nm IBM CMOS:
  - 55 x 55 µm^2 pixels
  - 1.5 ns time resolution → exceeds CLIC goals
  - P ≈ 350 mW / cm^2 → meets CLIC goals (with power pulsing)
- CLICPix (prototypes ≈2014) in 65 nm:
  - 20 x 20 µm^2 pixels

Low-mass interconnects between senor+readout:
- Cost driver → needs further R&D
- Technologies: Through-Silicon Vias (TSV), 3D interconnects, edgeless sensors, stitching of CMOS arrays



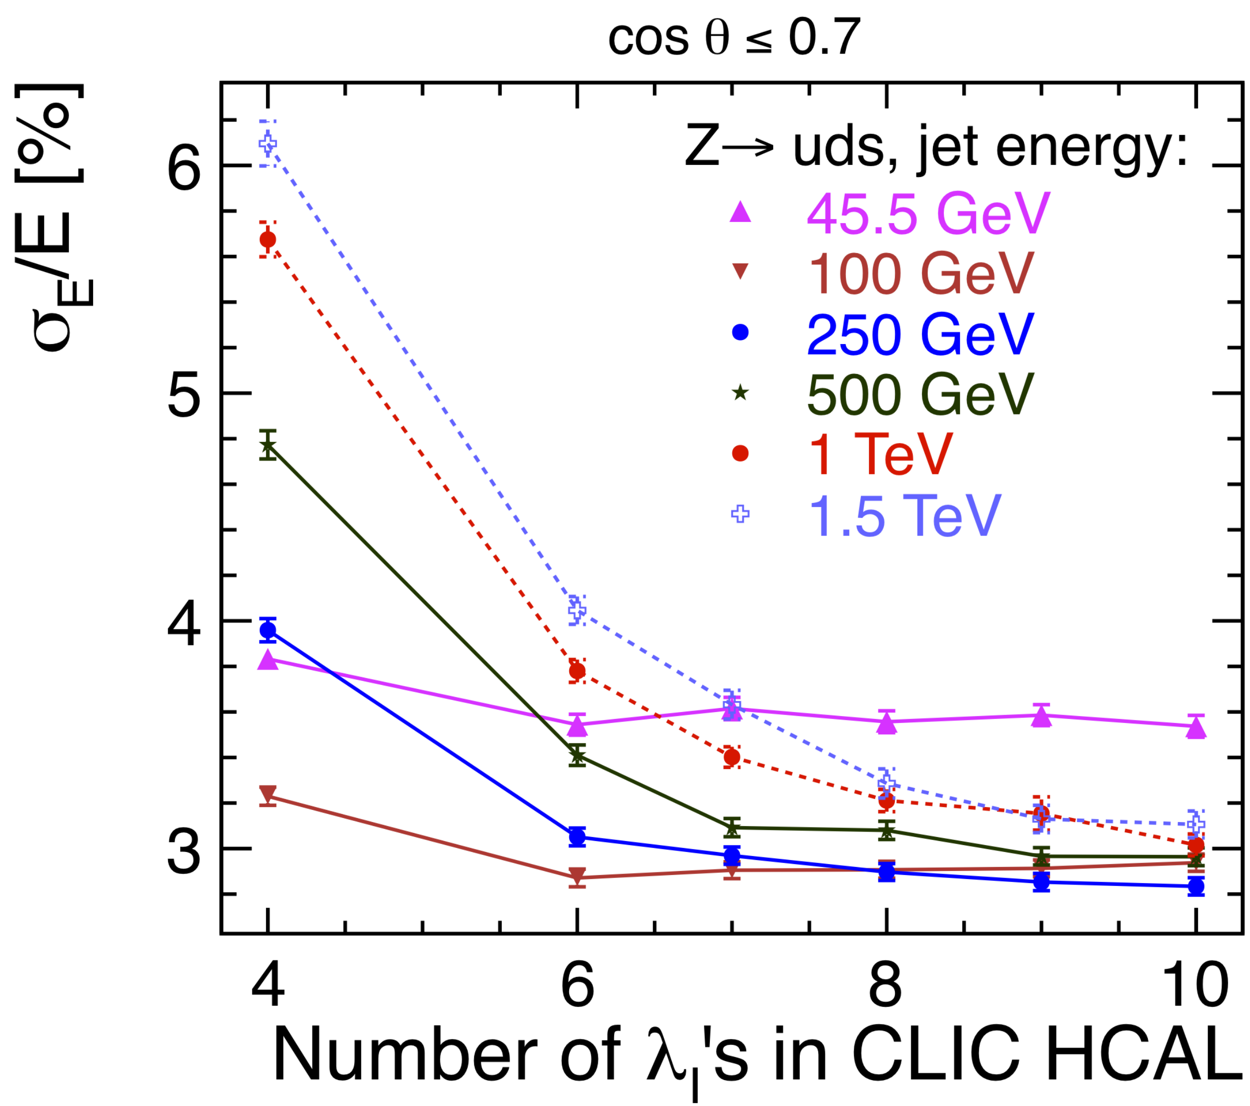
Examples for integrated approach

• Several active R&D programs (targeted to ILC requirements)

• Attempts to reach faster signal collection and ns time-stamping capability (compatible with CLIC requirements):

- **MIMOSA CMOS** chip family (currently 350 nm): developing high-resistivity epitaxial layers, smaller feature sizes
- **Chronopixel CMOS** sensors with fully depleted epitaxial layer
- **INMAPS** technology: deep p-well barrier protects n-well charge collector, improves charge collection, allows for high-resistivity epitaxial layer and full featured CMOS MAPS technology
- **High voltage CMOS:** CMOS signal processing electronics embedded in reverse-biased deep n-well that acts as signal collecting electrode
- **Silicon-On-Insulator (SOI)**: ≈200 nm SiO_2 isolation layer separates charge collection and readout functionality
- **Full 3D-integrated pixel sensors:** Thinned high-resistivity sensitive tier coupled to additional tiers with advanced analog+digital functionality

HCAL resolution

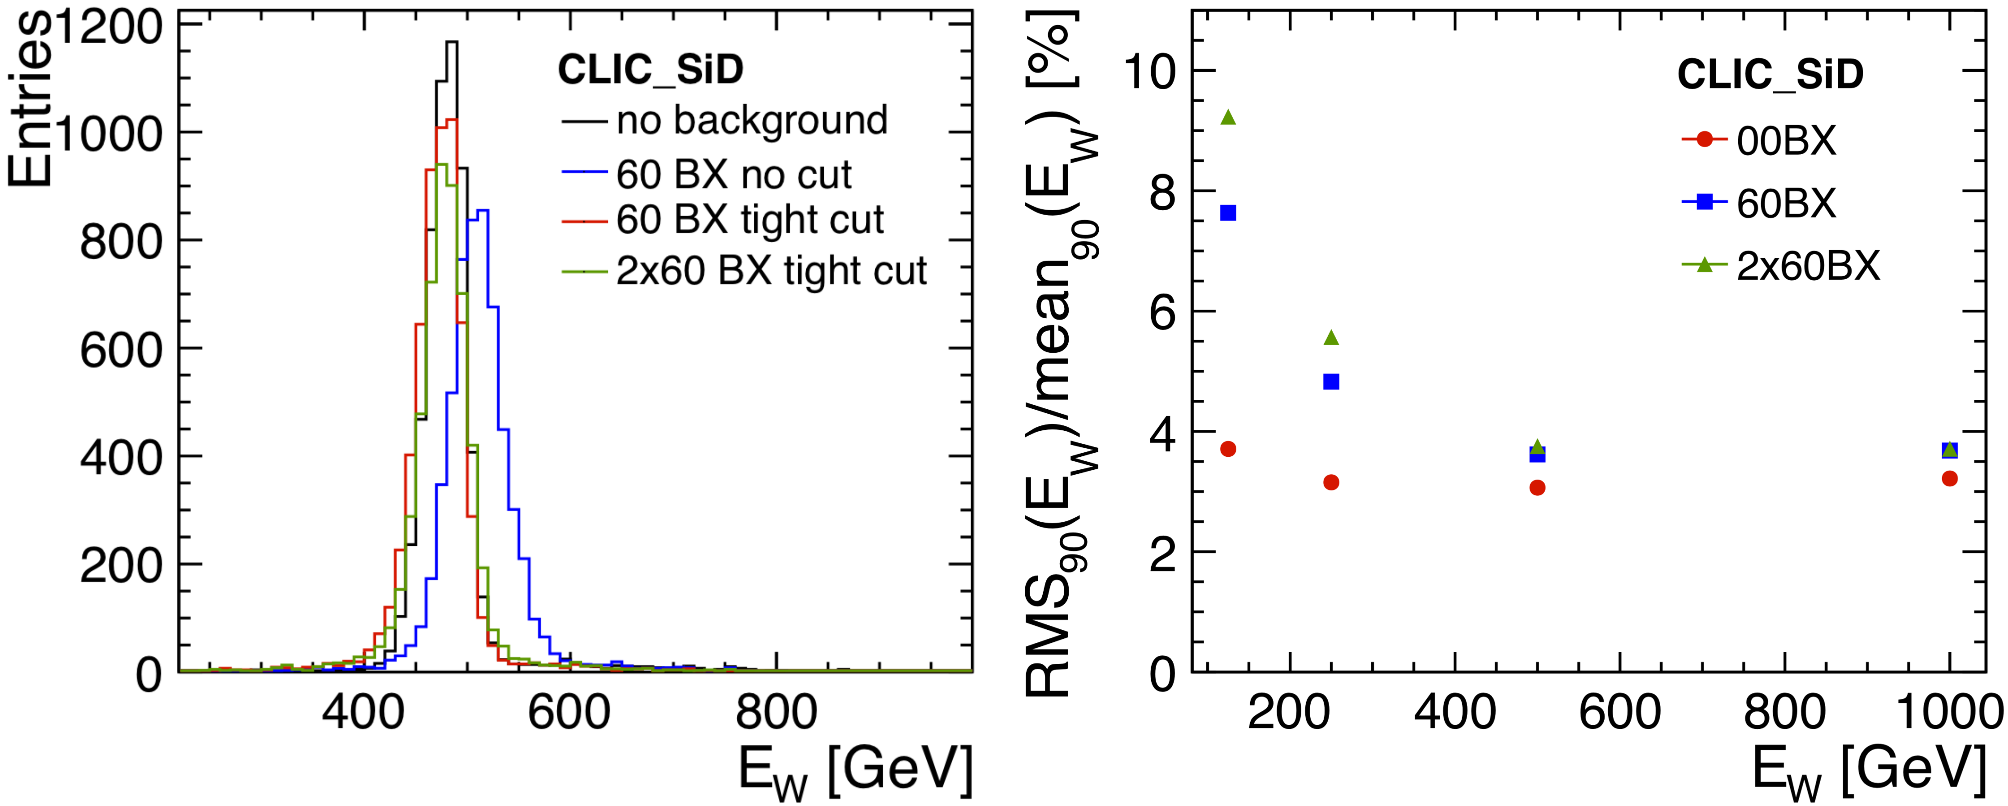


PFO based timing cuts

Region	p_t *range*	Time cut
Photons		
central ($\cos\theta \leq 0.975$)	$0.75\text{ GeV} \leq p_t < 4.0\text{ GeV}$ $0\text{ GeV} \leq p_t < 0.75\text{ GeV}$	$t < 2.0$ nsec $t < 1.0$ nsec
forward ($\cos\theta > 0.975$)	$0.75\text{ GeV} \leq p_t < 4.0\text{ GeV}$ $0\text{ GeV} \leq p_t < 0.75\text{ GeV}$	$t < 2.0$ nsec $t < 1.0$ nsec
Neutral hadrons		
central ($\cos\theta \leq 0.975$)	$0.75\text{ GeV} \leq p_t < 8.0\text{ GeV}$ $0\text{ GeV} \leq p_t < 0.75\text{ GeV}$	$t < 2.5$ nsec $t < 1.5$ nsec
forward ($\cos\theta > 0.975$)	$0.75\text{ GeV} \leq p_t < 8.0\text{ GeV}$ $0\text{ GeV} \leq p_t < 0.75\text{ GeV}$	$t < 2.0$ nsec $t < 1.0$ nsec
Charged PFOs		
all	$0.75\text{ GeV} \leq p_t < 4.0\text{ GeV}$ $0\text{ GeV} \leq p_t < 0.75\text{ GeV}$	$t < 3.0$ nsec $t < 1.5$ nsec

- Track-only minimum p_t: 0.5 GeV
- Track-only maximum time at ECAL: 10 nsec

Influence of pileup



W$^+$W$^-$ and ZZ

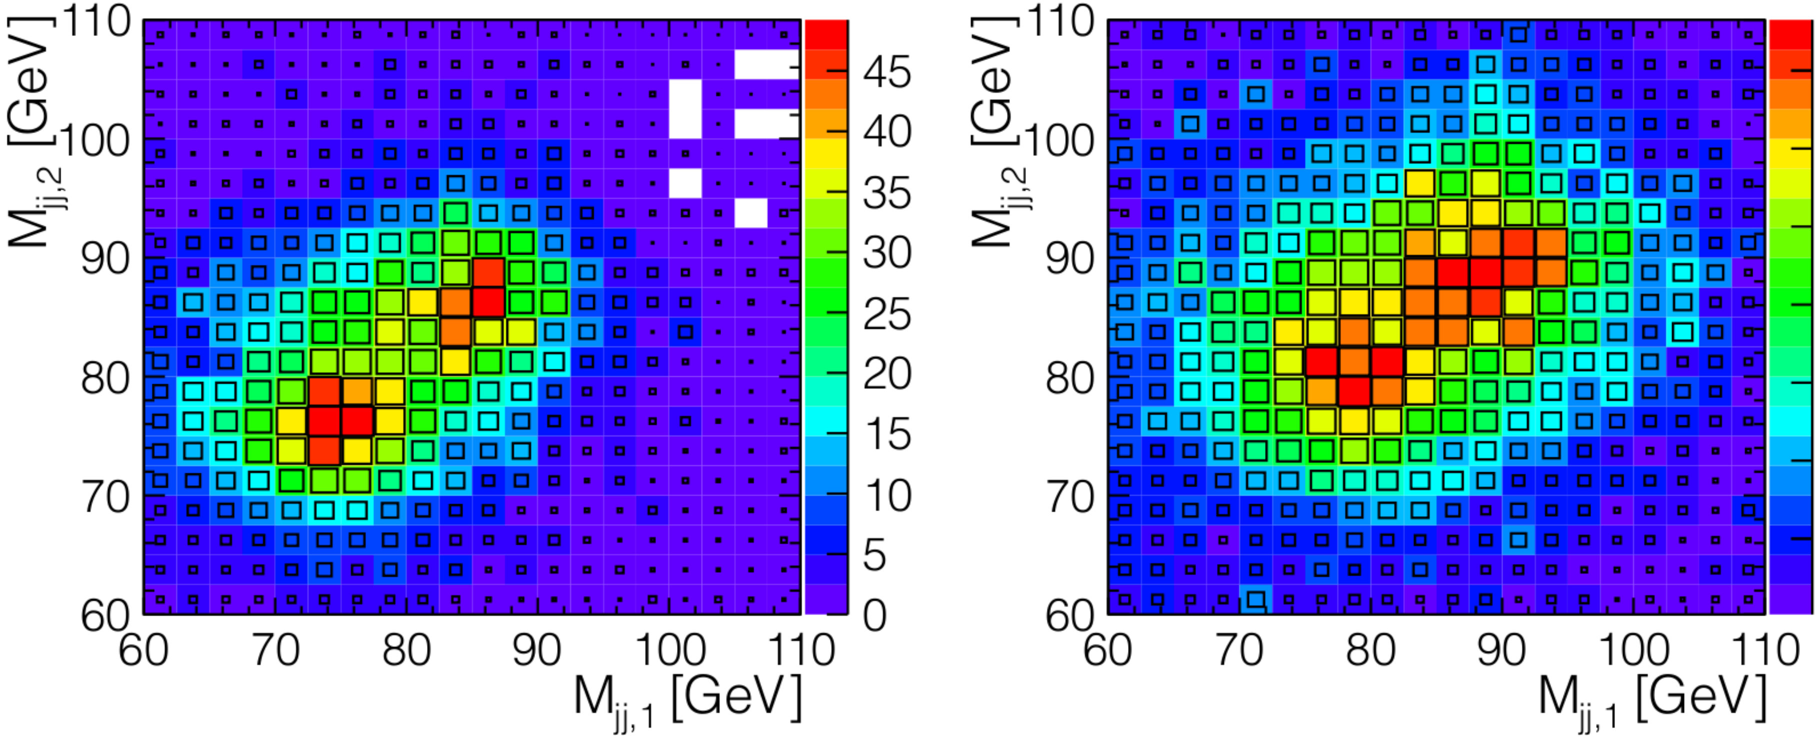


Figure 19: Separation of W and Z from the chargino decay without overlay (left) and with 60 BX of background (right) for CLIC_SiD.
